Guidance at a glance: executive summary

WHAT TO MEASURE?
The guidance provides recommendations for answering the following questions:
- How many people were reached with anticipatory actions (AA)?
- How timely were the AA? Did assistance arrive earlier than it would normally have?
- To what extent did AA achieve the intended results? Can changes in household-level outcomes, if any, be attributed to the AA intervention?

HOW TO ASSESS?
This guidance recommends assessing the effects of AA using a quasi-experimental approach, that is, by measuring differences in outcomes, if any, between beneficiary households and a comparison group of similarly vulnerable and disaster-affected households who only received traditional disaster response (non-AA beneficiaries). This is aligned with WFP's Corporate Monitoring Strategy which encourages the use of comparison groups for impact assessment.

WHEN TO COLLECT DATA?
This approach requires collecting sample survey data from FbF beneficiaries and comparison households at least once at endline, and ideally also at baseline if feasible. In drought contexts, a midline survey, for example, in the form of an outcome PDM, is recommended for one-off or recurring interventions that are designed to cover a longer period of time, else the drought conditions might erode benefits that may have been observable previously.

WHAT ARE THE CAPACITY REQUIREMENTS?
The suggested approach is fully aligned with existing WFP M&E processes and tools, including the organization's increasing attention to comparison groups for impact assessment. Depending on the types of AA chosen by the CO, some outcome indicators (e.g. related to livestock productivity) may be non-standard to WFP and will require some customization. Moreover, testing for statistical significance is an important part of intervention-comparison group analysis. In case in-house time or capacity are limited, CO teams may consider hiring temporary support using the available FbF project funds to support the design or implementation of their AA activation M&E.

WHAT RESOURCES ARE AVAILABLE?
Developing an M&E Framework is an integral part of the systems-building component of FbF interventions. As such, funds for both the design and implementation of M&E frameworks and tools should be budgeted under the (multi-year) capacity strengthening funding of FbF. In case of a forecast trigger activation and where M&E resources may not be sufficient, COs can include additional M&E budget (i.e. tools development, data collection costs, data analysis and reporting) in their internal funding request to HQ (Pro-C Unit) for anticipatory action funds allocation. Alternatively, COs can also benefit from the expertise of the Office of Evaluation, which is currently collaborating with PRO-C/PRO-R on the Climate and Resilience Evaluation Window, where consistent approaches are being developed and support to COs who are embarking on similar approaches as the ones proposed in this guidance note.

STEP-BY-STEP GUIDANCE
A. Planning and setting up the M&E system
1. Review the AA SOPs and logframe (Annex 1) to ensure results and indicators are aligned with the ToC (Figure 4). A minimum set of indicators to be monitored is proposed in the Annex.
2. Develop an M&E plan (Annex 2) based on the SOPs and logframe. Align choice of indicators (recall periods!) with timing of data collection and when outcomes (results) are expected to materialize.
3. Ensure implementation monitoring forms and processes are defined and ready.
4. Plan for outcome data collection and analysis. See C. below and prepare questionnaires, data collection and analysis according to research design. See also timing of data collection decision matrix (Annex 4).
B. Activity implementation, process and output monitoring
   1. Monitor timeliness: keep timeline of events. → Anticipatory action log (Annex 3)
   2. Monitor outputs and reach. → Standard output monitoring; basic monitoring form for timeliness and reach (see example in online resource folder).
   4. Consider periodic check-ins, where relevant.
   5. Consider alternative data sources and opportunities to generate insights.

C. Assessing household-level effects
   1. Choose a research design. → A quasi-experimental approach is recommended; research design outline (Annex 6).
   2. Define a sampling approach. → Sample size should be sufficient to detect significant differences based on expected effect size.
   3. Tailor data collection tools to actions, results and context. → Questionnaire design (example in online resource folder).
   4. Collect data. → Surveys should cover beneficiaries and comparison households, at endline and ideally baseline.
   5. Analyse data. → Test for statistically significant differences in outcomes between beneficiaries and comparison group.
   6. Conduct Focus Group Discussions to triangulate findings from outcome monitoring surveys (FGD Guide in Annex 5).

D. Learning
   1. Review and interpret data and draw conclusions about the FbF programme. → Lessons learned workshop guidance (Annex 7).
   2. Prepare, share and discuss findings with key audiences, including affected people.
I. Introduction: FbF, M&E, slow and fast-onset hazards

A. Forecast-based Financing

Forecast-based Financing (FbF) is a programmatic approach to anticipate disasters and mitigate their impact. FbF relies on in-depth risk analysis to design and implement anticipatory actions (AA) before a severe weather event occurs. Pre-planned and financed activities are undertaken once a forecast trigger reaches a critical threshold, indicating a high likelihood of an extreme weather event becoming a humanitarian disaster. By acting early, FbF programmes aim to avoid or reduce human suffering and losses instead of waiting for negative impacts to materialize and focusing exclusively on emergency response operations.¹

WFP has implemented FbF since 2015 in a growing number of countries that are prone to recurrent climate-related shocks. FbF programme activities are closely aligned with national priorities, leverage local field expertise and build on existing coordination mechanisms. FbF strengthens host governments and partners’ capacities to reduce, anticipate and rapidly respond to the effects of climate shocks before a hazard causes large-scale negative humanitarian impacts.

WFP’s FbF approach is integrated within a continuum of early warning, anticipatory action, recovery and resilience programming. Anticipatory actions are usually geared towards protecting lives and livelihoods, agriculture and food security in the short and medium term. To strengthen local capacities, WFP collaborates with national and local government partners to strengthen forecasting systems and access to information to enable quick, efficient and effective decision-making that is based on credible forecasts and pre-agreed danger thresholds or triggers.

The overarching goal of WFP’s FbF work is to provide communities and households with the resources needed to strengthen their capacity to absorb the effects of hydrometeorological hazards. WFP’s anticipatory actions aim to maintain and ideally improve the food security status of households and to protect their lives and livelihoods. A range of forecast-based actions are conceivable, depending on the nature of the hazard; for fast-onset hazards such as floods and cyclones, actions must be very quick, for example, early warning dissemination and rapid cash-transfers. For drought, actions range from information dissemination (e.g. seasonal bulletins and early warnings), distribution of inputs (e.g. seeds; fertilizer), cash or in-kind transfers (e.g. food; animal feed) to infrastructure rehabilitation (e.g. water sources; food storage facilities) and asset creation programmes.

<tr>
<th>Terminology: Anticipatory Action (AA) and Forecast-based Financing (FbF)</th>
</tr>
</thead>
<tbody>
<tr>
<td>For WFP, AA are predefined actions taken (1) based on defined thresholds from forecasts and risk analyses, (2) in anticipation of predictable hazards, so as to (3) prevent or mitigate the risk or impact.</td>
</tr>
<tr>
<td>AA can be delivered through FbF mechanisms. FbF releases funding and enables implementation of community-level actions in the critical window between a forecast and an extreme weather event. It consists of (1) forecast triggers, (2) AA, (3) pre-arranged financing, and (4) an M&amp;E framework.</td>
</tr>
</tbody>
</table>

¹ For an introduction to the FbF approach and its application in different contexts see WFP (2019), Forecast-based financing (FbF) - Anticipatory actions for food security, and WFP (2019), Climate Risk Financing: Early Response and Anticipatory Actions for Climate Hazards which illustrates the differences between AA, early response and traditional post-shock response.
B. Importance of M&E for FbF

The humanitarian sector has extensive experience responding to the impacts of hazards and large-scale humanitarian emergencies, whether caused by floods and cyclones or because droughts give rise to severe food insecurity, epidemics or conflict. There is also a large body of monitoring and evaluation (M&E) results and research on the effects of emergency response on the lives and livelihoods of those affected by the crises.²

Much less evidence exists on the effects of anticipatory humanitarian action. Several studies assess the benefits of AA in anticipation of extreme floods or cold waves³, and only very few examine drought-related anticipatory actions.⁴ With FbF being considered an innovative approach and a relatively recent addition to the humanitarian sector, it is necessary to generate robust evidence on the effectiveness of AA, also compared to conventional humanitarian response, and to learn what works and how to do better.

C. Purpose of this guide

This document seeks to offer practical guidance and examples for monitoring and evaluating anticipatory actions for slow and fast-onset hazards, helping to answer the overarching question of “Does FbF make a difference to reduce or mitigate the impacts on affected populations?”. The primary audience are WFP M&E and Programme staff in country offices (COs), although the methods and tools compiled in this guide should be useful to anyone working on M&E of anticipatory action.

The forecast-based nature of an FbF programme, the short lead times of fast-onset hazards and the complexity of drought contexts imply several particularities for M&E that are considered in this guide. Instead of aiming to be an exhaustive programme or project M&E manual – which would require repeating existing guidance available elsewhere – this document focuses on the particular M&E challenges posed by anticipatory action for slow and fast-onset hazards.⁵ It does not prescribe a particular approach or

³ In July 2020, a CERF-funded trigger of anticipatory actions to prevent extreme flood impacts in Bangladesh generated a number of evidence products on FbF interventions, most importantly: Pople et al. (2021), Anticipatory cash transfers in climate disaster response. For peer-reviewed studies see, for example, Gros et al. (2019), Household-level effects of providing forecast-based cash in anticipation of extreme weather events: Quasi-experimental evidence from humanitarian interventions in the 2017 floods in Bangladesh; Gros et al. (2020), The effectiveness of forecast-based humanitarian assistance in anticipation of extreme winters: Evidence from an intervention for vulnerable herders in Mongolia.
⁴ FAO has published several booklets about the effects of Early Warning Early Action work ahead of severe drought, see: FAO, Impact of Early Warning Early Action: Horn of Africa (2018); Madagascar (2019); Sudan (2019); Philippines (2020).
⁵ This guide does not provide general introductions to FbF or programme M&E. It is assumed that the target audience – being FbF and M&E practitioners at country level – already have the requisite foundational knowledge.
method, but flags key issues, provides perspectives for consideration and points to useful resources and further reading to allow FbF teams to make informed decisions about how to set up their M&E.

The examples and tools in this guide are built in a modular fashion so that country teams can adapt and use them in their programme settings. All content is based on practical experience from FbF programmes and built on existing organizational policy, guidance and M&E practice.

**Feature 1: Focussing on household-level effects of anticipatory action**

In addition to implementing anticipatory actions, WFP's FbF projects typically invest in complementary work to strengthen systems, capacity, and to connect WFP's FbF programme with early warning systems, social protection schemes, vulnerability analysis and other mechanisms such as cash-based transfers and asset creation activities. While these enabling programme components are very important for the success of an FbF initiative, a wealth of resources exists covering M&E of capacity and systems strengthening interventions.1 This document focuses on measuring **household-level effects**, assessing to what extent providing anticipatory assistance makes a difference to the affected vulnerable populations.

The examples and tools provided in this guide are informed by WFP's existing FbF projects but remain relevant for all WFP COs as well as external partner agencies and practitioners implementing anticipatory actions for slow and fast-onset-hazards. WFP's focus on safeguarding and strengthening the well-being, food security and livelihoods of disaster-affected populations shapes this material's thematic orientation. However, the general methodological approach will be applicable to a broader range of outcomes beyond food security and livelihoods.

The climate **hazards** discussed in this document are guided by what WFP country offices work on: mainly **floods and cyclones** in the fast-onset category, and **drought** as the only slow-onset hazard (WFP currently does not implement anticipatory actions for cold waves). Therefore, 'drought' and 'slow-onset hazard' are sometimes used interchangeably in this guide.

**D. Building on existing policy, guidance and practice**

**WFP M&E:** This document draws on and presumes that WFP staff are familiar with the organization's core guidance on monitoring and evaluation, particularly as it relates to programmes and indicators focused on food security, livelihoods and resilience:6

- WFP normative framework for monitoring by COs:
  - Minimum Monitoring Requirements (MMRs)7
  - CRF Indicator Compendium
  - Monitoring Standard Operating Procedures (SOP)

---

6 Web links related to WFP policies and guidance may be internal to the organization and accessible to WFP staff only. Users not connected to the WFP intranet may see an error message when opening such internal links.

7 For WFP staff, the MMRs are supplemented by the Corporate Monitoring Strategy and a suite of Corporate Monitoring Guidance. The Monitoring Foundations e-learning course is another useful resource for WFP staff and partners.

† For example, World Bank (2009), The Capacity Development Results Framework: A strategic and results-oriented approach to learning for capacity development. INTRAC (2010), Monitoring and Evaluating Capacity Building: Is it really that difficult?
Evaluation and assessing effectiveness:

- WFP Evaluation Policy (2016-2021)
- Evaluation Charter (OED 2016/007)
- Decentralized evaluation mini-guide for WFP management at country level

**FbF and M&E:** WFP’s CRF was updated in late 2020 to include selected indicators related to anticipatory action. Several of these are highly relevant for the purpose of this guide, especially: “Number of people covered and assisted through Forecast-based Anticipatory Actions against climate shocks” (CRF ref. G.9); “Number of people provided with direct access to information on climate and weather risks” (CRF ref. G.8); and “Percentage of planned tools developed or reviewed to strengthen national systems for Forecast-based Anticipatory Action” (CRF ref. G.7).

As described above, the purpose of this guide is to go beyond counting outputs to understand whether AA makes a difference to hazard-affected people. It is also worth noting that the other new CRF indicators on FbF – such as the one on strengthening national systems for AA – are not discussed further in this guide because its focus is to measure household-level effects, not systems changes or the performance of the forecast trigger system.

The remainder of the document is structured as follows: Section II puts forward guiding considerations on the ‘what’ and ‘how’ to monitor AA and to assess their effectiveness. Section III provides step-by-step suggestions for M&E planning, activity and output monitoring, outcome assessment and learning. The Annexes contain the examples and tools used throughout the guidance document.

---

8 The CRF Logframe Business Rules are formulated to inform the design of the Country Strategic Plan (CSP) logframe, and also make reference to “conventional” humanitarian response. Some rules will not be applicable to forecast-based interventions that are implemented at relatively short notice in an area that is not precisely known in advance. For example, rule (xii) stipulates that baselines should be established for all outcome indicators “no later than 3 months before and after an activity start as part of the CSP development process”. Rule (xvii) states: “For sudden humanitarian responses implemented for less than six months, performance measurement should focus at output and process level. If the emergency activity is extended beyond 6 months, measurement of the outcome level becomes mandatory. Pre-assistance baseline should be established regardless of the duration of the emergency response.” Section II discusses the practical feasibility of baseline data collection for FbF interventions, while section C reviews options for measuring outcome-level results.
II. Acting in anticipation: main implications for M&E

As indicated above, this document does not prescribe a specific M&E approach or method. Instead, it wants to enable FbF programme teams to make informed decisions about how to set up M&E for their interventions, and to put useful tools into their hands. Therefore, this section discusses foundational issues that are important to consider when planning and establishing an M&E process for FbF.

A. Slow and fast-onset hazards

Conventional humanitarian response is undertaken when a disaster has already occurred and impacts are visible. In contrast, anticipatory action for slow and fast-onset hazards happens under the uncertainty that the forecasted event might not come to pass, and it must be implemented in the window of opportunity between issuance of the forecast and the expected onset of the climate shock.

Figure 1 illustrates the differences in timelines between droughts and fast-onset hazards such as floods and cyclones.

Forecasts of fast-onset hazards typically give anticipatory humanitarian actors a relatively narrow window of opportunity of a few days to several hours to take action. The time constraint limits the choice of anticipatory actions that can be undertaken. The period within which physical impacts occur – from a cyclone making landfall or a land area being flooded – is usually short, from a few hours to days, sometimes weeks in case of severe and prolonged or repeated flooding. Since the anticipatory actions are usually designed to avoid or mitigate the impacts occurring in this short time period, the timing of data collection is typically linked closely to the timing of the extreme weather event.

Droughts are highly complex phenomena. While ‘drought’ generally refers to acute water shortage and a decrease from the expected average of water resource availability over a certain period of time, today it is not understood as a one-off natural disaster anymore but a natural cycle that can be worsened depending on a range of hydro-meteorological and socio-economic factors.

Given the complexity of drought as a meteorological event with hydrological and agricultural implications, it is more challenging to determine when the ideal time is to deploy anticipatory actions to mitigate drought impacts and to assess the intended and unintended effects that anticipatory actions have on the affected population. By extension, it is important to determine when and how measuring results is most sensible in light of the specific drought context and selection of anticipatory actions. The same applies to fast-onset hazards.

---

Figure 1: Timeline comparison of fast-onset hazards vs. droughts (illustrative example)

B. Differences in action lead times and implications for baseline data collection

As with ‘conventional’ humanitarian and development interventions, it is important to determine whether forecast-based actions achieve their intended results. This is done by collecting and analysing output and outcome-level data on the AA, using appropriate indicators as defined in the project logframe. Many humanitarian and development interventions establish baseline values for these indicators at the start of the programme or project. The purpose of a baseline is usually (a) to know the context in which an intervention takes place and (b) to determine a reference point (the starting conditions) against which a future situation will be compared.

For FbF interventions, the feasibility of baseline data collection depends on the lead time between forecast trigger and action implementation: FbF programmes are implemented based on weather or climate forecasts indicating where the hazard impacts are expected to be greatest. This implies that, in many contexts, the intervention area is not usually known in advance with a high degree of certainty. This, in turn, can put limitations on the practical feasibility to collect baseline data.

Regarding the lead time between forecast and action, or readiness trigger and action trigger, this can be weeks to months for drought, thus affording sufficient time for baseline data collection. However, for floods and cyclones, the window of opportunity between forecast and action is typically only a few days to several hours for these fast-onset hazards, making baseline data collection logistically impossible for specific intervention areas.

In case baseline data collection is not feasible:

- Secondary data on vulnerability and hazard exposure are already built into the SOP trigger mechanism that informs the decision on when and where to act based on a forecast. For example, available data might include indicators on protracted food insecurity, or population...
groups dependent on rain-fed agriculture, for example, from the last CSP follow up/endline survey or VAM population-based data. This can be useful as an estimate of average conditions at the time when the AA activation is triggered. The usefulness of the data as a baseline for a specific AA intervention will depend on when the data were collected (should be near the start of the AA implementation) and their granularity (requires household level data on the beneficiary population, from the same geographic area).

- **Beneficiary selection can be an opportunity for baseline data collection:** The anticipatory action SOPs must include criteria and an operational process for how AA beneficiaries are selected. The eligibility or targeting criteria are typically based on the same type of vulnerability information used to define the trigger system and applied at the individual or household level. This means that the criteria-based process to select households or individuals to benefit from AA provides an opportunity to also collect data relevant to the result indicators in the logframe.

> It is worth noting that a baseline-endline (before-after) comparison alone is neither strictly necessary nor sufficient to ascertain a cause-and-effect relationship between the intervention and an observed outcome if not also complemented by a comparison vis-à-vis the counterfactual of what would have happened in the absence of the anticipatory intervention, for example, if people had received only post-disaster assistance (discussed in more detail in ‘measures of success’ below). Baseline or ‘starting conditions’ can be estimated in later surveys using recall questions.

In case baseline data collection is possible:

- **Follow standard baseline data collection procedures:** WFP’s MMRs recommend baselines to be established three months before or three months after the start of the activity as per CRF business rules pertaining to the Country Strategic Plan. According to the MMRs for the CSP, these baseline values may be pre-assistance, or first monitoring values, depending on the indicator. For a one-off AA intervention, these rules are unlikely to apply.

- **To assess the counterfactual, collect data from beneficiaries and a comparison group of non-AA-beneficiaries** who received disaster response assistance ‘as usual’. This allows to compare the average change over time in the outcome indicators for the beneficiary group to the average change over time for the comparison group and assessing whether these changes can be attributed to the intervention, an approach also known as Difference in Differences (DiD), as illustrated in Figures 5a and 5b. This approach could imply a larger data collection exercise with implications for time and cost.

- **Align baseline data collection with beneficiary targeting.** There are three possible scenarios:
  
  i. **Beneficiaries are yet to be selected.** A baseline survey can be used to develop (if not already defined in the SOP) or fine-tune the selection criteria. This would require a large sample size because it can be expected that not all households who were interviewed will be eligible for AA assistance. Therefore, their information would not be usable as baseline data for AA beneficiaries.

  ii. **Beneficiary selection criteria are developed but beneficiaries have not yet been selected.** Baseline data collection can serve as a ‘screening’ opportunity to help identify the beneficiaries (e.g. by location, or by identifying the proportion of sub-groups to be included).

  iii. **Beneficiaries have already been selected.** In some country contexts, government authorities do the beneficiary selection, or community self-targeting mechanisms are used.
In these situations, the baseline data collection can be used as a verification exercise, to ensure selected beneficiaries meet the criteria.

A final note on the temporal aspect of baseline (and any other) data, since forecast-based actions and the measurement of their results are understandably time sensitive:

A dataset captures a snapshot of a moment or period of time. It is crucial to understand the situational context reflected in the data: Do they represent pre-disaster conditions or a status quo that has already been affected by the hazard? Was data collected at a time that can be thought of as the “prevailing normal” or exceptional in any way? And lastly, when was the data collected in relation to the FbF system trigger?

From an M&E perspective, baseline data would ideally reflect the situation immediately before anticipatory actions are implemented, acknowledging that it would require an agile approach to collect data from a representative sample of people during the time between AA being triggered and before actions are implemented.

C. When results are expected to emerge: timing of outcome data collection

The assumptions about the benefits of AA will differ depending on the type of anticipatory actions to be taken. For example, a cash distribution ahead of a cyclone to enable households to pay for evacuation transport, or to afford food or medical care in the aftermath, can show an immediate effect on their health and food security – for as long as the money lasts. In contrast, the duration and severity of a drought are typically unknown at the time when forecast-based actions are implemented. Anticipatory interventions must thus be designed based on assumptions when and for how long the actions will yield the greatest benefit for the targeted population, and when the benefits of the assistance can be expected to have fully materialized. For example, the results of distributing drought-resistant or fast-maturing seeds or fertilizer may only become fully appreciable during the next growing season or after the harvest.

Therefore, the timing of M&E efforts must be decided based on (a) the timing of the anticipatory actions and (b) the assumptions about the objectives pursued by the intervention, including the timing of the benefits accruing to the disaster-affected population. Figure 2a shows a hypothetical timeline of seasonal patterns for drought, the calendar of agricultural activities and the timing of AA; it also illustrates how the timing of data collection can be decided based on when results (household-level effects) can be expected to materialize. Figure 2b shows the same for fast-onset hazards.

The timing of data collection should be aligned with the type of anticipatory actions and the timing when results are expected to have fully materialized, not to the hazard context. This is particularly evident for slow-onset hazards: the beginning and end of a drought period, to the extent that it can be clearly defined at all, are not necessarily the times when meaningful data about results can be collected.

For example, Post-Distribution Monitoring (PDM) can be conducted shortly after an AA intervention, such as a cash transfer, for process and output monitoring (e.g. to measure beneficiary access to and use of the resources provided), while an outcome survey would be conducted at the end of the time period for which the benefits of the cash amount (e.g. maintaining the beneficiaries’ food security) are expected to last.

For fast-onset hazards and AA that are intended to mitigate immediate impacts from a flood or cyclone, results data would usually be collected soon after the flood has receded, or the
The cyclone has passed. For **anticipatory drought actions**, for example distribution of fast-maturing seeds, the results in the form of a (better, stabilized) harvest might only be observable much later in the season.

Figure 2b illustrates that **timescale considerations differ considerably** for fast-onset hazards. These hazards occur within a week, days, or hours of a forecast. The effects are immediately felt and can have medium to long-term impacts in the post-disaster and recovery phase. Compared to drought anticipatory action, fast-onset hazard programmes generally have one readiness trigger at the beginning of the hazard season (e.g. monsoon or cyclone season) and/or whenever seasonal forecasts are published. Then, anticipatory action is generally triggered between 7 days and 24 hours ahead of the event. This timescale context has implications for the timing of M&E: baseline data collection is either not feasible, or has to be

---

11 Adapted from the WFP Drought Anticipatory Action Standard Operating Procedures (SOP) Template. Seasonal calendars for many countries, similar to this one, can be found on the Famine Early Warning System website: [https://fews.net](https://fews.net)
done before the hazard season begins, which means that there is a possibility that areas and populations covered by the baseline survey will not be affected by the hazard and the data will not be used. While process PDM is done as usual, outcome monitoring is typically done, at a minimum, as soon as it is safe to enter the affected area and results have fully materialized, and possibly also at a later time to assess any longer-term effects of AA. For example, assuming that a pre-hazard cash transfer enabled vulnerable households to bring their crops or seed stock to safety, one could expect higher incomes and/or agricultural yield in the weeks and months following the disaster, once market and productive activities have resumed. Therefore, outcome monitoring three to six months after the AA and extreme event can generate relevant data on results with a causal link to the anticipatory intervention.

The timing of M&E efforts and choice of methods will also depend on whether the anticipatory actions are implemented as one-off or recurring interventions. Typically, FbF programmes aim to pre-plan and pre-finance impactful one-off actions that can be implemented quickly as soon as the forecast triggers the activation based on a critical threshold. In a drought context, an anticipatory cash transfer might be deployed one-off at the onset of the rainfall period, or in monthly tranches for the most severe two to three months of the drought. It is also important to note that AA might be activated following, or in parallel with, other programmes such as Lean Season Assistance (LSA) or Food Assistance for Assets (FFA). Therefore, M&E aimed at measuring the effects of AA must be able to do so while being cognizant of the influence of other interventions benefitting the same population group. Otherwise, the data would most likely reflect the compounding effect that AA has in conjunction with other assistance.

The M&E plan of the intervention must take into account whether AA are one-off or recurring, and be able to account for the influence of other interventions (see Figures 2a and 2b for illustrative timelines).

- **Baseline data** can provide a historical point of reference and information on the starting conditions of the beneficiary population, and ideally of a comparison group of an equally vulnerable and drought-affected population. A baseline survey can also be used to ascertain whether and when the survey population accessed benefits of other programmes (see following sub-section for a more detailed discussion). Looking at the example in Figure 2a, the baseline survey would be conducted in June for drought FbF, just before the first intervention, e.g. a cash transfer, is implemented, and before or at the beginning of the cyclone or monsoon season for fast-onset FbF (Figure 2b).

- **Process PDM** can accompany staggered or recurring interventions, for example, monthly cash transfers in advance of and during the drought period. The data can yield valuable insights to help steer the intervention implementation. For example, in Figure 2a, process and output monitoring are done in August and December, after the drought intervention roll-out has begun, or whenever possible during the fast-onset AA implementation (Figure 2b). In case the data reveal inefficiencies or problems with the distribution process, COs can use this information to make adjustments to the ongoing or the upcoming implementation operation.

- **Outcome PDM** can serve as midline stocktaking and is particularly useful in contexts where the anticipatory actions are intended to sustain benefits over an extended period of time. In the Figure 2a example, outcome PDM for drought FbF is conducted in November and February, following the completion of the first and second intervention (e.g. cash transfer) implementation periods. The PDM data can confirm whether the expected immediate benefits – such as access to food – are materializing. In an extreme drought context, the PDM findings also ensure that interim results are recorded before they may be eroded by worsening drought conditions. Process and outcome PDM can be combined.
An outcome survey at endline is best conducted when the intended effects of the intervention have fully materialized. For example, if the objective of the intervention(s) is to maintain people’s food security throughout the priority impact period, one would measure the food security status at the end of this time period and hope to see the results to be in the targeted value range. In case a baseline was conducted, ideally the endline is conducted during the same period to avoid seasonal effects. Figure 2a shows that, in this example, the endline survey is conducted in June of year 2, after all interventions are completed and the critical period has ended during which the AA were meant to mitigate negative drought impacts; this is also the same month when the baseline survey was conducted during the previous year. However, when conducting an endline survey more than three months after the intervention completion, it must be considered whether AA benefits will still be visible, measurable and/or recallable by survey respondents. Therefore, the survey could also be conducted sooner if seasonality effects can be controlled for through the survey questionnaire. In the case of fast-onset FbF (Figure 2b), the outcome PDM or endline survey can be undertaken soon after the flood or cyclone event, once the results are expected to have fully materialized; a second outcome PDM can be considered to measure longer-term effects, as mentioned above. Outcome surveys and Outcome PDM also serve to inform integrated resilience programmes where evidence on the use of FbF for slow and fast-onset hazards can be instrumental to resilience building in the medium and long term.

It is not required to conduct four surveys to assess the effectiveness of the FbF intervention. At a minimum, it is suggested to conduct one outcome survey at endline. If baseline data collection is feasible, it is recommended to also collect baseline data.

D. Measures of success: reach, outputs and timeliness; outcomes; attribution

The rationale for FbF is that it enables WFP and its partners to act earlier than they would normally do. Therefore, knowing when and how many people were reached with assistance is particularly important for M&E of both drought and rapid-onset FbF. Monitoring outcomes allows WFP to assess if the expected results can be observed among beneficiaries; and causal attribution analysis enables WFP to understand if the observed results can be ascribed to the AA intervention.

Figure 3 illustrates that the three measures of success build on each other: the disaster-affected population must be reached by the AA timely enough for the intended outcomes to occur – according to the ToC of the intervention. WFP's process, output and outcome monitoring practices provide the requisite data. Attribution analysis assesses the extent to which observable outcomes are caused by AA.
i. **Reach, outputs and timeliness (process/output monitoring)**

At the most basic level, M&E mechanisms must be in place to measure three fundamental parameters:

- **Reach:** How many individuals and how many households were assisted through forecast-based actions and across which geographic area? Did they face challenges or protection concerns accessing assistance? Also, in case the forecast-based intervention consists of multiple actions, for example, cash-based transfers and distributions of non-food items (NFI), it is important to avoid double-counting beneficiaries.\(^\text{12}\)

- **Outputs:** For AA, the following standard WFP output indicator groups are likely to be the most common to be tracked: resources transferred, nutritious food provided, assets created, and communication delivered.

- **Timeliness:** The “cost” of forecast-based humanitarian action is the risk of acting in vain because of the uncertainty attached to the weather prediction.\(^\text{13}\) However, the cost of uncertainty should be more than compensated by the advantage of being able to act before conditions become extreme. **Therefore, it is essential to track the time when AA reaches the beneficiaries, both in absolute dates and relative to (a) the forecast trigger and (b) the evolution of drought conditions or the fast-onset hazard** (for example, when a cyclone makes landfall, or a flood reaches peak levels).

Data on the reach and timeliness of AA is easy to generate when planned for in advance. Basic record keeping and monitoring of action implementation provide information on how many people benefitted and the extent to which the actions can be considered timely in relation to the hazard context. FbF programme managers can keep a simple diary of important forecast information, pivotal decisions and actions that were taken.

Annex 3 provides a template and example of such an ‘anticipatory action log’. Moreover, depending on the delivery modality of the anticipatory actions, implementing partners can be asked to keep track of how many beneficiaries were reached every day or week using standard distribution monitoring formats. WFP has developed a range of activity implementation monitoring tools that can be used for this purpose.

---

\(^{13}\) Therefore, it is generally recommended to choose “no regrets” actions that contribute toward building resilience and have a positive effect on the beneficiaries even if an extreme weather event does not occur.
ii. Outcomes

Building on the understanding of when, where and how many people were reached by AA, an important learning priority is to understand whether the expected outcomes are observable among the beneficiary population. This document uses the term ‘outcome’ broadly to refer to the status of and changes in the experience, behaviour or capacity of the target group. Outcomes are results beyond the direct control of the AA intervention.

In the context of FbF for slow and fast-onset hazards to safeguard food security and livelihoods, it is important to note that ‘no change’ in status or behaviour may be a desirable result, for example, a maintained Food Consumption Score (FCS) at the ‘acceptable’ level or the continued avoidance of food-based coping strategies.

Beneficiary outcomes at the household level should be measured using WFP’s corporate monitoring tools whenever possible. A wealth of survey instruments is referenced in the MMRs, the Monitoring SOP, the suite of Data Collection Tools for food and cash-based transfers, and the Resilience Toolkit.

When outcome data is collected from AA beneficiaries only (the survey sample is drawn entirely from FbF intervention recipients), it will not be possible to determine the extent to which observable results, if any, can be attributed to the FbF intervention. Therefore, this document includes recommendations on using experimental or quasi-experimental methods\(^{14}\) to understand the contribution of AA to the achievement of outcomes.

iii. Causal attribution of outcomes

A result cannot be claimed to be the effect of anticipatory actions unless there is a demonstrated causal link between the result and the AA intervention. An essential feature of experimental and quasi-experimental methods is that they not only measure or describe changes that have occurred but also seek to understand the role of particular interventions in producing these changes. This process is often referred to as causal attribution, causal contribution or causal inference.\(^{15}\) An overview of different strategies is provided in Feature 2.

---

14 See Feature 2 for alternative approaches to causal attribution analysis. Quasi-experimental methods tend to be the most readily accessible and implementable approach for humanitarian organizations implementing FbF.

15 For a good overview of different approaches to causal attribution and references to further reading see: Rogers, P. (2014), Overview: Strategies for Causal Attribution. UNICEF methodological briefs, impact evaluation no. 6.
Feature 2: Strategies for causal attribution

Several different strategies may be used to undertake causal attribution. Each has its own strengths, limitations and suitability according to the specific programme context. One can broadly distinguish three types of approaches:

- **Counterfactual approaches** arrive at an estimate of what would have happened in the absence of a programme or intervention and compare this to what was observed in the presence of the intervention. This approach requires collecting data from a control or comparison group, except when relying on statistical modelling only. The two most commonly used study approaches are experimental designs (both beneficiaries and control group members are randomly chosen, a method also referred to as Randomised Controlled Trial or RCT) and quasi-experimental designs (comparison groups are constructed in various, mostly non-random ways).

- **Consistency of evidence with causal relationship** identifies patterns that would be consistent with a causal relationship, which is usually grounded in a well-developed theory of change, and then seeks confirming and disconfirming evidence. This requires a combination of different methods to achieve robustness. Options include checking results against expert predictions, existing literature, timing of impacts, comparative case studies, process tracing and qualitative comparative analysis.

- **Ruling out alternatives**, an approach which identifies possible alternative causal explanations and seeks information to see if these can be ruled out. Methods include key informant interviews, process tracing, modelling and a general elimination process.

*Source and further details: Rogers (2014)*

Experimental study designs are commonly considered to offer the highest internal validity to assess whether an intervention made a difference. Internal validity refers to the accuracy of determining a cause-and-effect relationship between the intervention (AA) and the outcome of interest (for example, food security). However, a truly experimental study design requires that the members of the beneficiary group and the comparison group are randomly selected. COs may find it difficult to implement full randomization, for example, because limited funding does not allow to follow the more detailed and time consuming research requirements, or because political agreement to conduct a randomized experiment can be challenging to obtain.

For the majority of contexts in which FbF is currently applied, the most practical strategy to causal attribution appears to be a counterfactual approach using a quasi-experimental research design to estimate what would have happened without anticipatory actions. A quasi-experiment offers some simplifications because it does not require randomization, and many COs and programme teams already have the key pre-requisites in place: experience in collecting household survey data, and knowing where and how to hire additional capacity for sampling, surveying or statistical analysis tasks if needed. In contrast, the more specialized qualitative research skills that are required to implement alternative causal attribution strategies rigorously may be less widely known or accessible to country teams. Therefore, the remainder of this document uses a quasi-experimental study approach as the reference method. A carefully managed quasi-experimental study is also well aligned with the WFP Impact Evaluation Strategy (2019-2026) which encourages the use of ‘credible counterfactuals’. The strategy also underscores the importance of robust evidence generation for AA, given that climate change and resilience are evidence priorities under the strategy.

---

16 WFP has developed a [Blended Course on Qualitative Research](#) for staff, with additional training materials under development.
It is recommended to compare anticipatory action with conventional humanitarian response, or whichever intervention is considered ‘normal’ in the given context, to assess whether AA or an alternative mode of assistance has more impact on food security in a drought or fast-onset hazard context. This is typically referred to as ‘multiple treatment arm study’ and can be combined with the neutral counterfactual. In this case, data would be collected from three groups: (i) AA beneficiaries, (ii) intervention B beneficiaries, and (iii) the ‘no treatment’ group. When the comparison group represents the neutral ‘no treatment’ situation, it is possible to measure the absolute effect of the FbF assistance on beneficiary outcomes.

In practical terms, this means that, in addition to collecting data on outcome indicators from FbF beneficiaries, outcome data should also be gathered from a comparison group of individuals or households that share the same socio-economic characteristics and are equally drought-affected as the intervention group that receives forecast-based assistance. This is well aligned with WFP’s Corporate Monitoring Strategy 2018-2021 in which the increased use of comparison groups is one of the main results to be achieved under workstream 3.3 (Enhance Use, Credibility and Relevance of Outcome and Process Monitoring).

For additional information see Annex 6: Research design and analysis plan outline (example).\(^{17,18}\)

It is also conceivable to compare the effectiveness of different FbF ‘packages’ to each other in the same intervention context, to identify which type of assistance is most impactful. For example, beneficiary group A could be given an unconditional cash grant of USD 100, while beneficiary group B receives USD 50 in cash plus USD 50 worth of livestock feed or drought-resistant seeds. Alternatively, in a slow-onset situation, one group could receive USD 100 at once at the beginning while the other group receives USD 50 first and USD 50 a bit later. The value of the assistance would be identical in both cases, but the configuration would be different. The choice of who receives which ‘package’ could be randomized at the household, community, or district/regional level.

Feature 3: Research ethics in humanitarian contexts

Recognition of the need for evidence-based interventions to help improve the effectiveness and efficiency of humanitarian action has been growing.\textsuperscript{17} Research approaches such as quasi-experimental designs can be suitable to generate this much-needed evidence. While any research involving human beings must fulfil ethical standards, this holds particularly true for research with people affected by humanitarian crises.

The United Nations Evaluation Group (UNEG) has issued general UNEG Ethical Guidelines to steer evaluative research conducted by the UN system. Several other agencies have developed ethical guidelines specifically for research in humanitarian settings that also apply to M&E efforts conducted based on this guidance.\textsuperscript{18} Important principles include informed consent, ‘do no harm’, respecting people, their culture and customs, and responsibilities for general and public welfare.

The notion of quasi-experimental research sometimes evokes scepticism among agency staff based on ethical grounds: Collecting data from a comparison group means asking crisis-affected people to respond to interview questions although they did not benefit from a particular humanitarian intervention. In light of this legitimate concern, here are three issues for consideration:

(1) It is the prerogative of the local decision makers of the FbF programme whether a quasi-experimental study approach is practical or not. The well-being and safety of everyone involved – the crisis-affected population, agency staff and data collectors – are always the highest priorities.

(2) People affected by disasters deserve effective humanitarian actions that promote health, well-being and livelihoods, respect dignity, and uphold rights. Research that generates robust evidence to help distinguish effective from ineffective interventions can make a significant contribution toward impactful, ethical, anticipatory humanitarian action.

(3) Funding for humanitarian interventions is limited, especially for AA. Unfortunately, it appears almost certain that this situation will prevail for the foreseeable future. Not everyone who is forecasted to be affected by an extreme weather event and who will require assistance will be reached by AA because of a lack of resources. For quasi-experimental research to work, much-needed assistance will not be willfully withheld from anyone. Funding amounts are simply too small to reach everyone in need. Very unfortunately, there will be disaster-affected people who did not receive AA – and constitute a potential “comparison group”.

To illustrate the types of outputs and outcomes to be achieved and measured, the following section reviews two simplified theories of change, one each for a slow and for a fast-onset AA intervention.

E. Theory of change and logical frameworks

The development of a theory of change (ToC) is the starting point to understand and visualize the causal linkages between an intervention and the intended results. Figures 4a and 4b outline simplified ToCs of WFP FbF drought and flood/cyclone projects, based on AA interventions in several countries. The logical framework\textsuperscript{19} then defines how the outputs of different activities contribute to the achievement of the expected results. For each level (output, outcome and impact), the logframe defines the indicators to be measured and the targets to be achieved. For an FbF intervention, this information is

\textsuperscript{19} The terms ‘logical framework’ and ‘logframe’ are used interchangeably in this document. Both refer to the matrix that captures programme or project results, indicators, baseline and target values, and assumptions, while an M&E plan adds further detail to the logframe by defining data sources, reporting responsibilities and frequencies.
defined in the AA SOPs that describe the activities to be implemented, intended beneficiaries, operational and financial requirements.

WFP’s normative framework for monitoring\(^\text{20}\) provides detailed guidance and resources for developing logical frameworks. This section offers stylized ToCs and logical frameworks (Annex 1) for anticipatory action to avoid or mitigate disaster impacts, based on a review and synthesis of planned and ongoing FbF interventions. The examples can be further tailored to specific country, hazard and socio-economic contexts.

**FbF interventions to reduce drought impacts**

The main objective of WFP’s drought FbF interventions is to reduce impacts on vulnerable smallholder farmers. Most of WFP’s FbF projects have prioritized droughts’ disruptive effects on livelihoods, primarily agricultural production, and food security, as shown in the integrated ToC depicted in Figure 4a. Not every action will be implemented or applicable everywhere. FbF country teams will design anticipatory action plans that are tailored to their specific drought and socio-economic contexts, delivering the results that are most relevant for their target groups.

A range of anticipatory actions are conceivable to support livelihoods and food security: disseminating information, offering training, in-kind or cash transfers, and asset creation schemes, among others, to provide farmers with the awareness, know how, inputs or financial resources to drought-proof their farming practices and livestock management and to have continued access to nutritious food. The actions are intended to help farmers stabilize or even increase their farm output, which is expected to positively affect income and access to nutritious food. This should also reduce the need to resort to high-risk coping strategies such as selling valuable assets or resorting to lower quality food. At the same time, anticipatory cash transfers can put fungible resources into the hands of vulnerable households for productive investments or consumptive spending for food access.

The types of anticipatory actions to be implemented and the outputs to be delivered lend themselves to fairly standard monitoring practices, albeit under the time and planning challenges discussed in the following sub-sections. At the outcome level, the interventions seek to change behaviours of how smallholder farmers cultivate crops, manage livestock and the food consumption patterns of drought-affected households. **While activity implementation and output delivery can be tracked via action records and field/process monitoring, survey-based approaches are more suitable for measuring behavioural changes.**

Annex 1 illustrates how a logical framework can be composed following the example of the ToC (Figure 4a), based on the existing WFP FbF project country experiences. The logframe assigns indicators for each intended result, showing how progress and success or failure can be measured. The example also includes an overview of the assumptions underlying the results chain.

---

\(^{20}\) See references and document links in the introduction.
AA differs from other Disaster Risk Management (DRM) or Social Safety Net (SSN) interventions that WFP undertakes, both in timing and objectives:

(a) **Timing:** AAs are implemented ahead of an extreme weather event, when a specific weather forecast indicates that a hazard of a particular severity is likely to happen within a given time period, rather than wait for the hazard to occur or for the impacts of the event to be visible.

(b) **Objective:** AAs are intended to prevent or mitigate the impact of an extreme weather event before it strikes. They are not meant to: i) respond to peak needs when or after they materialise (as in emergency response), or ii) address seasonal food gaps or chronic vulnerabilities that exist regardless of a climatic shock (as in safety nets, including LSA).

(c) AA also differs from (and should not substitute) other multi-year interventions that aim to reduce disaster impacts in the long-term (such as asset creation/FFA) regardless of a particular forecast. In this regard, **AAs are intended as short-term and/or "one-off" interventions** that can cover some of the residual risks that have not been reduced by longer-term investments in DRM or resilience-building interventions.

Anticipatory actions for fast-onset hazards: floods and cyclones

Given the much shorter lead time between the trigger, implementation of fast-onset AA and the expected impacts from a flood or cyclone making landfall, the anticipatory actions illustrated in the ToC in Figure 4b focus on dissemination of early warnings, multi-purpose cash distributions, and in some cases trainings or advisory, for example, on flood preparedness measures. Similar to the drought ToC, the fast-onset actions aim to enable vulnerable people to take pre-emptive actions and have access to the goods and services they need to avoid or mitigate potential negative impacts from the anticipated flood or cyclone. This is to protect their health, well-being, assets and livelihoods.
Drought FbF M&E Guide

Figure 4a: Simplified, integrated theory of change of WFP FbF drought projects (see Annex 1 for corresponding logframe with CRF references, including assumptions)

**ANTICIPATORY ACTIONS**
- Provide households with...
  - Information
    - Weather advisory to farmers
    - Early warning
    - Mitigation measures
    - Coping strategies
    - Livestock and animal health
    - Crop pest management
  - Training
    - Drought tolerant/short season seed varieties
    - Drought-adapted cultivation techniques
    - Marketing
    - Livestock health
    - Pest management
  - In-kind/cash distribution
    - Drought tolerant/short season seed varieties
    - Fertilizer
    - Supplementary animal feed
    - Animal health supplies
    - Crop pest management supplies
    - Cash transfer
  - Construction/asset creation
    - Water point rehabilitation
    - Water capture and storage (food/cash assistance for water conservation asset creation)
  - Discretionary buying power
    - Productive inputs
    - Food
    - NFIs
    - Medical expenses
    - Education expenses
    - Etc.

**OUTPUTS**
- Immediate outcomes
  - Awareness
    - Drought risk
    - Nutritional benefits of small grains
    - Alternative coping strategies
    - Animal health
    - Pest level monitoring
    - Improved farming practices
      - Use of improved seeds
      - Appropriate use of fertilizer
      - Practicing conservation agriculture
      - Effective pest control
  - Know how
    - Seed varieties
    - Cultivation techniques
    - Marketing agricultural products
    - Animal health management
    - Pest control
    - Adaptive livestock management
      - Proactive animal health management
      - Destocking
  - Access to and use of essential goods and services
    - Nutritious food
    - Household necessities
    - Equipment
    - Health care
    - Education
    - Etc.

**IMMEDIATE OUTCOMES**
- Resulting in...
- Intermediate outcomes
  - Strengthened resilience of agricultural production
    - Increased diversification of agricultural production with drought tolerant varieties
    - Stabilized or increased seed stock for next growing season
  - Stabilized agricultural output
    - Production of drought tolerant varieties stabilized or increased
    - Household livestock productivity stabilized or increased
  - Maintained household food consumption
    - Consumption of nutritious food maintained or increased
    - Drawing on own production or market access
  - Reducing use of high-risk coping strategies
    - Maintained/reduced food expenditure share
    - Avoiding destitution sales of valuable assets and high interest borrowing
    - Reducing meal quality or frequency

**IMPACT**
- Increased resilience to drought shocks
  - Stabilized income of smallholder farmers
  - Maintained or increased food security
  - Coping capacity of households maintained/increased (livelihood coping strategies)
Figure 4b: Simplified, integrated theory of change of WFP FbF fast-onset hazard projects (see Annex 1 for corresponding logframe with CRF references, including assumptions)

**ANTICIPATORY ACTIONS**

**Early warning**
- Household-level dissemination of early warning (SMS, voice calls)

**Trainings**
- Orientations on flood preparedness for local disaster management committees

**In-kind/NFI distribution**
- Flood-proof containers (for food, inputs)
- Flood proofing materials

**Cash distribution**
- Unconditional
- Multipurpose
- Focused

**OUTPUTS**

**Outputs (immediate)**
- Provide households with...
  - **Early warning**
    - Understanding of hazard
    - Knowledge of intensity, magnitude and location of forecasted hazard
    - Understanding of potential impact

- **Trainings**
  - Pre-emptive actions taken
    - Removal of people, livestock, and valuables to safe places
    - Pre-stocking of essential items
    - House elevation, wall and roof reinforcement

- **In-kind/NFI distribution**
  - Access to and use of essential goods and services
    - Food and water
    - Healthcare
    - Education
    - Equipment
    - Other daily necessities
    - Etc.

- **Cash distribution**
  - Discretionary buying power
    - Food and water
    - Cleaning items (hygiene and house)
    - NFIs
    - Medical expenses
    - Etc.

**OUTCOMES (immediate)**

Which enable them to...

**OUTCOMES (intermediate)**

- Resulting in...

**IMPACT**

- Strengthened post-shock resilience
  - Maintained household food security
  - Maintained or better mental and physical health outcomes
  - Stabilized household incomes
  - Coping capacity of households maintained/increased
  - (livelihood coping strategies)

- Reduced use of high-risk coping strategies
  - Maintained/reduced food expenditure share
  - Avoiding destitution sales of valuable assets and high interest borrowing
  - Avoid reducing meal quality or frequency
  - Education continuity

And contributing to...

- More effective disaster response
  - Reduced pressure on response teams and activities
  - More capacity for targeted interventions
F. Setting indicator targets

Irrespective of whether baseline values are established, an FbF intervention should set targets for “how much” the AA are expected to achieve. As this document focuses on household level effects in the event of an activation, the discussion on setting targets is framed in this context.

Several different ways are conceivable to decide upon the indicator target values in the logframe:

- **Absolute values** can be defined, for example, as minimum or maximum desirable threshold for each indicator (“at least 80% of beneficiaries will have an ‘acceptable’ FCS”, or “at most 15% of beneficiaries will have a Food Expenditure Share (FES) greater than or equal to 65% of their monthly budget” following the intervention).

  It can be difficult to set absolute targets for drought FbF actions because the intervention effect will depend on (be relative to) the duration and severity of the drought. Both factors are not known in advance with any precision. Besides, while a high absolute target for an indicator such as the FCS is desirable, the achievement of that target alone does not preordain a conclusion as to whether this can be attributed to the FbF intervention.

- **Targets over baseline** are the most common form of relative target setting (for example, “15% above the baseline value”). While this alone is not generally recommended for FbF programmes because of the caveats discussed above, one can readily conceive of an approach that would gather baseline information – even from secondary sources that were established well before the FbF trigger (and thus may not reflect near-activation starting conditions) – and define discretionary targets vis-à-vis these baseline values.

- **Relative targets** can be set in relation to the counterfactual of “what would have happened without the FbF intervention”. This can be based on the risk analysis and drought impact estimates in the SOPs which might have revealed, for example, that 50% of households in the drought risk area are likely to face deteriorating food security if they remain without assistance.

  Since the counterfactual of ‘what would have happened without FbF assistance’ is not directly observable, the next-best solution is to collect data from a comparison group of equally vulnerable households that was equally affected by the drought but not reached by the FbF intervention; they should have received the same type of traditional post-shock response assistance as everyone else (the quasi-experimental approach discussed above). A relative indicator target could look like this: “The proportion of households with an ‘acceptable’ FCS will be 50% higher among beneficiaries than among comparison households”.

  Challenges can also arise when setting relative targets: the drought context and the comparison group(s) are dynamic and will evolve over time; estimating the likely effect size of AA can be difficult. The extent to which any effects can be measured with certainty will also depend on the sample size and the quality of the sampling process and the survey data to be collected (discussed in more detail in section III.C below).

Any one or a combination of the above target setting approaches may be suitable for an FbF intervention. The target column in the Annex 1 logframe example illustrates how relative targets can be set against the comparison group.

---

21 Annex 6, section 5 includes suggestions on how to identify a comparison group and ensure it is comparable on key characteristics.
G. Summary of M&E options and the recommended approach

Figures 5a and 5b provide visual summaries of the common options for generating evidence on drought and fast-onset FbF interventions, based on a hypothetical scenario of anticipatory actions for drought and flood/cyclone.

The top half of each figure shows the measurements of a given outcome indicator, for example, the FCS. The graph tracks the indicator values for two groups over time: FbF AA beneficiaries (blue dots) and non-AA-beneficiaries (in grey) who are equally vulnerable and likely to be disaster-affected but who will only receive traditional post-shock response together with everyone else. Notice how, on the left, the future beneficiaries and non-beneficiaries start out at about the same level. In the absence of an external shock or programme intervention, one can expect the indicator values to show slight variations as time passes: both groups register small increases in the outcome indicator until the first AA is implemented, for example, a cash transfer.

Drought example:
- The intervention is rolled out because the situational context is expected to deteriorate. Failing rains might leave herders without sufficient water and forage for their animals. Less income from livestock products can negatively affect their ability to afford sufficient nutritious food for their families. The FCS is likely to drop.
- The hypothetical case in Figure 5a indicates that the AA beneficiaries experience an increase in the FCS following the first cash transfer, thanks to the additional money used to buy food. At the same time, the food security of non-beneficiaries starts to decline. However, as the drought conditions continue – and possibly worsen – and the AA cash transfer is spent (presumably not only on food but also on other necessities), the FbF beneficiaries also see their food security weaken, albeit not at the same rate as the people who were not reached by AA.
- By the time the second cash transfer arrives near the middle of the drought period, AA beneficiaries are back near the indicator level at which the measurement started. The additional resources from the second AA give an immediate boost to their FCS, gradually wearing off as the drought conditions persist. Non-beneficiaries experience a continuing decline in their food security situation.
- It is usually not possible to observe the movements of outcome indicator values over time with as many data points as shown in Figure 5a. Outcome data are typically collected via surveys which require time and resources. The bottom half of Figure 5a indicates that data are collected four times in this example: a baseline and endline survey, and two PDM exercises are conducted in between. The outcome indicator data points measured through the four surveys are shown in darker shading in the top half of the figure, illustrating that – in reality – these would be the only known indicator values, everything in between would be unknown. It is also worth noting that WFP’s MMRs broadly distinguish between Process PDM and Outcome PDM. While process monitoring data is highly relevant to inform an ongoing intervention, the emphasis in this example is on outcome monitoring to measure AA results.

Fast-onset example (flood / cyclone):
- Figure 5b illustrates that the time between the activation trigger and the expected extreme weather event is very short, usually never more than seven days and often shorter. This leaves time for only one wave of anticipatory actions. If baseline data collection is desired, it must be done before or early (e.g. right before in the monsoon or cyclone season) and cannot be done after the trigger because time is too short. This is different from slow-onset FbF where there might be sufficient lead time to conduct a baseline survey.
FbF M&E Guide

- A common objective of AA for flood or cyclones is to protect the lives, livelihoods and assets of vulnerable households from catastrophic loss. For example, the outcome indicator in Figure 5b could be the level of a household's crop or seed stock which can be used for planting (that is, productive activity) or household consumption (thus ensuring food security).
- In the hypothetical scenario presented in Figure 5b, a cash transfer reaches vulnerable households two to three days before a cyclone makes landfall or a river reaches peak flood levels. Upon impact, many houses and farms will be destroyed, leading to a significant destruction or loss in household crop stocks. However, AA cash beneficiaries were better able to protect their assets by using the money to reinforce their houses or to move their goods to a safe area.
- A first round of outcome monitoring two to four weeks after the disaster may show the reduced levels of crop and seed stocks among AA beneficiaries and response-only (non-AA) beneficiaries. However, the AA recipients are more likely to recover faster because they can use their protected stocks either for consumption and/or for planting, thus resuming productive activity sooner. The magnitude of this benefit will only be visible at a later stage, for example, two to three months after the flood or cyclone occurred, as illustrated by the second round of outcome monitoring depicted in Figure 5b.

The conventional method for WFP to collect outcome data on interventions concentrates on beneficiaries before, during and after, eventually making ‘before-after’ (baseline-endline) comparisons, indicated as assessment option (1) in Figures 5a and 5b. The examples further illustrate what can happen when only relying on baseline-endline data from AA beneficiaries for a given outcome indicator: Since the anticipatory actions are implemented before a climate shock of unknown – but expected to be extreme – severity, the outcome indicators of interest might even record a lower score at the time of the endline measurement and only data from a comparison group can reveal whether AA was successful in preventing even more extreme losses (the counterfactual of what would have happened with response assistance only, assessment option 2).

Figure 5a: Slow-onset FbF, options for evidence generation, illustrated on a hypothetical FbF intervention scenario (objective: maintain a given outcome indicator on an acceptable level until after the drought period)
How does FbF M&E differ for slow and fast-onset hazards?

1. **Baseline data:**
   In most fast-onset hazard situations, there will not be sufficient time to collect baseline data because the time between forecast and action is too short, whereas this can be feasible in slow-onset drought contexts. It is still possible to determine the effect of AA in both scenarios when using a quasi-experimental approach that harnesses the power of comparison group data.

2. **One-off vs. recurring actions; likelihood of situational changes:**
   The lead time for fast-onset hazards is so short that only one round of AA can be implemented before a flood or cyclone, while multiple waves of AA are conceivable in drought contexts, as seen in Figure 5a. This is because a drought situation can persist for a long period of time, and because the severity and duration of a drought period may change from what was initially forecasted when the drought AA was first activated. Therefore, it may also be advisable to conduct several rounds of interim outcome monitoring to track indicators of time in a dynamic context.

3. **Timing of outcomes materializing, and outcome data collection:**
   Sudden-onset floods and cyclones are usually short-term climate shocks. Their direct impacts – and with them the effectiveness of AA to mitigate them – will be visible almost immediately. For example, the destruction of houses or agricultural fields can be assessed in near-real time, while indirect consequences are observable within days.
or weeks (for example, a cholera outbreak after a flood or crop losses because a cyclone destroyed storage facilities). **Outcome data** for fast-onset FbF is typically **collected soon after the disaster**, for example, within four to eight weeks, although this can vary widely by context. In the example shown in Figure 5b, the positive knock-on effects of AA – protecting food and seed stocks that can be used for household consumption and replanting of fields that were destroyed – will only be visible an additional **several weeks to months later**.

In contrast, the effects of **drought** on people’s lives and livelihoods can **take weeks or months to fully materialize**. Therefore, actions are typically designed to mitigate these slow-onset impacts, and **data** on the effectiveness of AA to avoid or mitigate drought impacts is often **collected over a period – or after – several months**, as discussed in section II.C above (timing of data collection).

The examples in Figure 5a and 5b show that, without data on the counterfactual (what would have happened with response assistance only, without AA), one would miss the fact that the AA intervention was successful in helping beneficiaries mitigate the worst disaster impacts. The outcome data from the **comparison group** (having received traditional post-shock response but not having received forecast-based assistance) indicate that the disaster impacts would have been much worse without AA, revealed by **assessment option (2)**.

In case data is collected from AA beneficiaries and a comparison group of non-AA-beneficiaries (traditional response only) in the baseline and endline surveys, a **DiD** approach can be used to calculate the effect of the intervention by comparing the average change over time in the outcome indicator for the beneficiary group to the average change over time for the comparison group, highlighted as **assessment option (3)** in Figures 5a and 5b.

The recommended option is to follow a **quasi-experimental approach** of measuring outcomes vis-à-vis a comparison group of similarly vulnerable and disaster-affected people who received conventional humanitarian response assistance but who did not benefit from the AA intervention.

**In slow-onset contexts where baseline data collection is possible, it is suggested to survey beneficiaries and a comparison group**. This constitutes the most robust – albeit the most resource-intensive – of the three options illustrated in Figures 5a and 5b because it allows for a DiD analysis approach.

The conventional method for WFP to collect outcome data on interventions concentrates on **beneficiaries before, during and after**, eventually making baseline-endline comparisons. In the context of AA interventions, there is a risk that this approach will not effectively capture FbF results.

**All three options should build on or be complemented by standard WFP process and outcome monitoring exercises** (PDM) to assess whether the interventions are reaching the intended beneficiaries and to take interim result measurements.

With the basic considerations discussed, the following section provides practical step-by-step suggestions for how to monitor drought FbF actions and assess their effects on the food security, livelihoods and well-being of the disaster-affected target population. FbF programme teams should be able to adapt these steps and resources, with some modification, to their specific context.
III. Step-by-step guidance for FbF M&E

The following suggestions assume that an FbF programme or project has already been established or is in the process of being designed. Ideally, M&E is part of the FbF planning process from the very beginning so that data, analysis and learning can be generated to inform decision about where, when and how to act in anticipation of hazards, both fast and slow onset.

The central reference point for the step-by-step guidance are the SOPs because they define the anticipatory actions to be taken when triggered by a forecast. These actions and their effects are the primary object of FbF M&E. Another important source of direction will be the logical framework of the FbF programme or project, which can be found either in the SOPs, the FbF project/programme document or the CSP.

A. Planning and setting up the M&E system

1. Review the SOPs and logframe to ensure results and indicators are aligned with the ToC

   The development of a ToC is the starting point for an FbF intervention and should inform the prioritization of anticipatory actions in the SOPs. As a next step, the logframe is created to translate the intervention logic into a results chain with indicators defined to track progress at each step of the way.

   An important ‘to do’ from an M&E perspective is to ensure that all indicators are clearly defined and measurable (see next step) as these will allow to test the ToC, including the hypotheses and assumptions.

2. Develop an M&E plan based on the SOPs and logframe

   See WFP (2017), Guidance on Developing Theories of Change. Useful examples can also be found in Hivos (2015), Theory of Change Thinking in Practice: A Stepwise Approach. Note that these could also be integrated with “resilience” theories of change as a way to increase household anticipatory capacity and limit the use of negative coping strategies, see WFP Resilience Toolkit.

**A. Planning and setting up the M&E system**

1. **Review the SOPs and logframe to ensure results and indicators are aligned with the ToC**

   The development of a ToC is the starting point for an FbF intervention and should inform the prioritization of anticipatory actions in the SOPs. As a next step, the logframe is created to translate the intervention logic into a results chain with indicators defined to track progress at each step of the way.

   An important ‘to do’ from an M&E perspective is to ensure that all indicators are clearly defined and measurable (see next step) as these will allow to test the ToC, including the hypotheses and assumptions.

   **Toolbox**

   - Drought FbF ToC (example in Figure 4a); fast-onset FbF ToC general guidance on developing ToCs available
   - Drought FbF logical framework (example in Annex 1); fast-onset FbF logical framework
   - Minimum set of indicators to be monitored (see Annex).
   - WFP CRF logframe template
   - WFP How to build your logframe in 16 steps (for corporate logframes)

2. **Develop an M&E plan based on the SOPs and logframe**

   See WFP (2017), Guidance on Developing Theories of Change. Useful examples can also be found in Hivos (2015), Theory of Change Thinking in Practice: A Stepwise Approach. Note that these could also be integrated with “resilience” theories of change as a way to increase household anticipatory capacity and limit the use of negative coping strategies, see WFP Resilience Toolkit.
Based on the ToC and logframe, it is advisable to develop an M&E plan that (a) clearly defines each indicator, (b) identifies a data source or method how data for the indicator will be collected, (c) when data will be collected, and (d) who is responsible for ensuring that data will be collected at the right time using the appropriate methodology. An example is included in Annex 2.

The development of the M&E plan is an important planning moment to reflect about when is the most appropriate time to collect outcome data. As discussed and illustrated in section II, the timing of survey activities should be planned according when the results can be expected to have fully ‘materialized’. The planning calendar can serve as a collaborative tool to facilitate a discussion with the FbF team and with affected communities about the timing of events and data collection activities. In addition, Annex 4 includes a matrix tool as a decision aid for when to collect data on results, with further details and guidance.

Ensure that the choice of indicators is aligned with the expected timing of data collection. The M&E plan development is an opportune moment to review this. Some indicators have specific recall periods\(^{23}\) which will be reflected in the data collection tools. Longer recall periods (between 3-12 months) better capture broader trends but are less sensitive to recent changes, while short recall periods (24 hours to 1 week) are very time sensitive.

However, all survey questions will be subject to recency bias – the cognitive tendency to favour recent events over more historic ones. Therefore, it is advisable to not delay outcome data collection for too long after the results are expected to have materialized, else they may be forgotten (and intended short-term gains may be eroded by, for example, unexpected and exacerbating drought conditions).

Baseline and endline surveys will generally contain all relevant outcome indicators irrespective of the recall period. For outcome surveys that are done immediately following a distribution (PDM), indicators with short recall periods, such as the FCS, might already reflect the effects of the latest intervention while metrics with longer recall periods, such as the LCS or FES, are less sensitive to recent changes.

Using the example presented in Figure 5a, the first PDM might use a shorter questionnaire focusing on process monitoring and selected outcome indicators with short recall periods. This is because a baseline survey was recently completed and behavioural patterns like coping strategies or general household spending may not have changed significantly yet, while the FCS (one week recall period) could already register an improvement thanks to the AA assistance. The second PDM can again include process monitoring questions and feature additional outcome indicators with longer recall periods to assess whether the first intervention was successful, for example, in helping beneficiaries avoid negative coping strategies over the preceding month or so. Therefore, PDM 2 in Figure 5a can be considered as a midline survey.

Here is an overview of the recall periods used in several key indicators at the household and community level:

**Food security:**
- Household Dietary Diversity Score (HDDS): 24 hours
- FCS and FCS-Nutrition (FCS-N): 7 days
- Food Insecurity Experience Scale (FIES, not a WFP CRF indicator): 1 month or 12 months, depending on the research and programme priorities

\(^{23}\) The ‘recall period’ is the time span referred to in a question which has to be remembered (recalled) by the respondent, for example, “how many times during the last 7 days”, or “in the last 24 hours, have you...”
- FES: Household expenditures are split into recall periods of 30 days (food basket), and 6 months depending on estimated frequency of purchase of non-food items or health and education expenditure.

**Coping strategies and livelihoods:**
- Consumption-based Coping Strategy Index (CSI): 7 days
- Livelihood-based Coping Strategies (LCS): 30 days
- Asset Benefit Indicator (ABI) and Environmental Benefit Indicator (EBI): *since the beginning* of the Food for Assets (FFA)/asset creation intervention (applicable to asset creation beneficiaries)

**Capacity to manage climatic shocks and risks:**
- Climate Capacity Score (CCS): The questions comprising this indicator are mostly binary ('does your community have access to...’ – yes/no), and for some items the recall period is three years.

  The CCS indicator as defined in the CRF is not ideally suited to measure the results of an AA intervention. It is better suited to measure systems-building aspects of anticipatory action, not the actions themselves. Indeed, AA is not a long-term capacity development programme but an ad hoc activity intended to mitigate the impact of an impending extreme weather event. However, specific CCS questions can be modified to apply in the AA context. For example, CCS question 1 asks: “Does the community have access to climate/weather information useful for livelihood decision making?”.

  If early warning or other weather information was part of the AA, the question can be modified to ask: “Did you receive an early warning in [time period of AA activation] informing you about heightened [drought/flood/cyclone] risk during [risk period]?”. Note here that an adapted version of the Subjectively Evaluated Resilience Score (SERS) could also be used to assess the capacity to manage shocks and different coping strategies.

- Planning calendar (example in Figures 2a and 2b)
- Timing of data collection decision matrix (Annex 4)
- Subjectively Evaluated Resilience Score (SERS)

#### 3. Ensure implementation monitoring forms and processes are defined and ready

A considerable amount of information can be collected when actions are being implemented. If anticipatory actions are carried out by implementing partners, as is often the case, it is important to agree in advance which data must be generated and at which frequency. At a minimum, weekly or even daily updates about the number of beneficiaries reached with assistance, and their location and at which time should be transmitted to WFP using process PDM tools or the example format provided in Annex 5.

When the mode of implementation allows for direct interactions with beneficiaries (as opposed to, for example, mobile money transfers of cash assistance), useful **additional information can be generated**, for example, about the perceived timeliness and utility of the AA. The forms and data collection processes (the ‘who’ and ‘how’) to do this should be developed during the planning phase, before an AA activation occurs.

Increasingly, **mobile data collection** (with questionnaires programmed into tablet devices or smartphones) and **remote surveying** means (through phone interviews or SMS polls) are gaining traction.
WFP has made guidance and tools available for these purposes (see toolbox). Their use is encouraged as it can speed up data collection processes, increase the quality of data thanks to the in-built data validation features, and lower the cost of data collection by reducing interview and travel times. FbF teams can deploy the forms included in this guidance document via WFP’s Mobile Operational Data Acquisition (MoDa), the organization’s version of Open Data Kit (ODK), to mobile devices for field data collection.

**Toolbox**

4. **WFP food distribution monitoring form**
5. **WFP Remote Monitoring Quick Guide**
6. **WFP Mobile Operational Data Acquisition (MoDa)**, the organization’s version of ODK
7. **WFP Data Quality Guidance**

### 4. Plan for outcome data collection and analysis

The decisions about the monitoring and research design – how, when and how often outcome-level results will be measured – are ideally taken at the planning stage, once the SOPs has been finalized. This is important to ensure that the FbF programme will have the requisite capacity for data collection and capacity for analysis in place when the time comes. Therefore, some of the process steps to be taken and tools to be designed that are mentioned in the ‘measuring household level effects’ section below are best tackled at this early stage, before a trigger occurs.

**Toolbox**
- → See toolbox under ‘Assessing household-level effects’ (page 36)

### B. Activity implementation, process and output monitoring

The following steps should be carried out once forecast-based actions have been triggered. Ideally, the planning to be ready for these steps is done before the trigger occurs.

1. **Monitor timeliness: keep timeline of events / anticipatory action log**

   The risk of AA to act in vain if a forecast was inaccurate is offset by the ability to act sooner than usual when the forecast conditions do occur. Therefore, it is very important for FbF programmes to generate evidence on the timeliness of their anticipatory actions.

   The timeliness of AA can be thought of in at least three dimensions:
   1. Timeliness in relation to **hazard and drought/flood/cyclone conditions** (for example, “for weeks after the last rainfall” or “with the beginning of the raining season” or “72 days before peak flood levels were reached”)
   2. Timeliness in relation to the **trigger** (for example, “7 days after the SOPs was activated”)
c) Timeliness according to beneficiary perceptions (for example, beneficiaries may perceive cash assistance to have come too late for their main expenditure needs, or seeds to have come too soon to be kept safe and in good condition until planting)

Timeliness dimensions (a) and (b) can best be tracked by keeping an Anticipatory Action Log; a rudimentary example is included in Annex 3.

The timeliness according to beneficiary perceptions (c) requires collecting feedback from beneficiaries. This can be done at the time of distribution, soon after, or as part of an outcome survey at a later time. In the latter case, not too much time should have passed between the distribution and the survey because the potential recall bias must be taken into account.²⁴

Toolbox
- Anticipatory Action Log (example in Annex 3)

2. Monitor outputs and reach

The reach of anticipatory actions refers to the number of beneficiaries receiving assistance and the geographic coverage of the interventions, i.e., where they live. This information is best captured as it is generated during distributions or other activity implementation. Implementing partners can use standard reporting processes, and the FbF team can record beneficiary numbers and locations in the Anticipatory Action Log.

An added benefit of entering and storing data electronically through tools such as MoDA (see above) and SCOPE (WFP’s beneficiary and transfer management platform) is that it can reduce the cost of data collection and entry and it can be readily visualized on a map – a powerful communication tool to show the reach of an intervention.

Toolbox
- Basic implementation monitoring form for timeliness and reach (example in online resource folder)
- Standard implementing partner reporting

3. Process monitoring

Process monitoring should follow standard WFP protocol. In addition, any interaction with beneficiaries can be an opportunity to collect useful data, for example, during or after anticipatory action implementation or once distribution activities are carried out. The additional data can inform the current implementation or future improvements of the AA design.

²⁴ A number of studies, mainly from the health sector, have shown that longer recall periods do not automatically translate into greater recall bias. The main take-away is that the recall period must correspond to the characteristics of the phenomenon of interest and the purpose of the assessment. A recent study with rural farmers in Bangladesh found that food expenditures and livelihood-related tasks (for example, the amount of time worked on farm) were recalled with considerable consistency over longer periods of time, while non-food expenditures and non-livelihood related questions seem to be more likely to be forgotten or mis-remembered. Bell et al. (2019), Assessing recall bias and measurement error in high-frequency social data collection for human-environment research, Population and Environment 40, 325–345. On flexible recall periods see Stull et al. (2009), Optimal recall periods for patient-reported outcomes: challenges and potential solutions, Current Medical Research and Opinion, 25, 4. See also Kjellsson et al. (2014), Forgetting to remember or remembering to forget: A study of the recall period length in health care survey questions, Journal of Health Economics, 25, 34-46.
For example, monitoring teams can collect initial reactions from beneficiaries about the perceived relevance and usability of the assistance provided, and they can highlight unforeseen constraints or opportunities that may affect the effectiveness of the anticipatory actions. For instance, if a cash distribution is meant to enable farmers to buy supplementary feed for their livestock, but feed is not available in the local market, the immediate feedback from beneficiaries can flag this supply shortage early on and enable the FbF team to explore alternative actions.

The type of operationally relevant information to be collected, if any, depends on the AA and the local drought context. Data can be collected in face-to-face interviews using the basic implementation monitoring form (see toolbox) or via periodic telephone check-ins with beneficiaries, with those who have phones and whose phone numbers have been collected during the registration or distribution.

4. **Consider periodic check-ins, where relevant**

WFP’s “regular” programmes have periodic monitoring requirements that are defined in the organization’s normative framework for monitoring by COs. While the timing of FbF interventions and their effects may be somewhat different, it is equally relevant for them to learn from the beneficiaries’ experiences.

The longer time horizon of droughts means that there may be room for “top-up” actions or mid-implementation course corrections. Therefore, instead of only planning for an initial process PDM effort and a final outcome survey, FbF teams may consider conducting periodic check-ins with beneficiaries.

The periodic check-ins can be set up with a randomly selected sub-set of beneficiaries and fielded via short phone calls or SMS polls. Key information to collect could pertain to (a) the status of local drought conditions, (b) agricultural activity, (c) food security, and (d) any other feedback or concerns.

5. **Consider alternative data sources and opportunities to generate insights**

There may be alternatives to collecting data directly from beneficiaries to generate insights that are relevant for programme decision making. For example, remote sensing – satellite or aerial imagery and drone footage – can provide information on real-time changes in drought conditions or agricultural activity (identifying fields where planting has begun; soil conditions; forage availability; or crop damages). Other humanitarian agencies with activities in the areas where the AA are implemented may be able to share data about local conditions or movements of people.

C. **Assessing household-level effects**

1. **Choose a research design**

The decision on how to measure the effects of AA on the disaster-affected population is the prerogative of the FbF team. The WFP minimum requirement is that outcomes are measured following the guidance in the normative framework. As discussed in section II, this guidance document proposes to go one step further and use a quasi-experimental study approach to assess whether observable outcomes can be attributed to the forecast-based intervention. This involves collecting household survey data from beneficiaries and a comparison group of equally disaster-affected and similarly vulnerable households that did not receive AA assistance. This can be people

In addition to household survey data, it is recommended to collect \textbf{qualitative data} that help contextualize the quantitative findings, yield richer contextual insights and contribute to answering the ‘why’ questions behind some of the key findings that emerge. For example, immediately once preliminary results from the quantitative survey data analysis area available, focus group discussions and key informant interviews can reveal why beneficiaries did or did not decide to spend their cash transfer resources on a particular purpose, or why agricultural inputs distributed via AA could not be used by the beneficiaries as foreseen in the SOPs (for further details see step 6 below).

\textbf{The timing of when outcome-level data are collected is very important}, as discussed in section II and should be built into the research design, based on the drought situation and informed assumptions about when results can be expected to have fully materialized. It may also be desirable to \textbf{plan for more than one outcome/impact assessment}, for example, a short-term assessment and a medium-term assessment to determine whether the immediate benefits of FbF assistance were retained or had an influence over a longer period of time.

\begin{itemize}
  \item \textbf{Annex 6} includes a research design outline with practical suggestions for \textit{how to frame the assessment approach}. Annex 6, section 5 includes suggestions on \textit{how to identify a comparison group}, which will involve a screening and listing of equally vulnerable and drought-affected districts, communities and households that were not reached with AA assistance.
\end{itemize}

    \item \textbf{Research design outline} (example in Annex 6)
  \end{itemize}
\end{itemize}

\section{Define a sampling approach}

Besides the resources available and the overall operational context, the sample size to be chosen depends on several factors:

- Geographic coverage and reach of the intervention (total population of interest)
- Acceptable margin of error and the desired confidence level
- The minimum effect size and the anticipated distribution of results (whether we expect 50\% of respondents to be food insecure or 90\% has implications for the required sample size)
- The specific sampling strategy selected following the ToC and indicator disaggregation requirements; for example, it is important to be aware that the sampling error will be affected by the number and size of strata and clusters in the sample (e.g. how many households are interviewed in each sampled community)
- Types of anticipatory actions and the FbF intervention eligibility criteria (also called beneficiary selection or targeting criteria) because they will determine how to identify a suitable comparison group

\textbf{The usefulness of a quasi-experimental design hinges on the ability to identify statistically significant differences between the FbF intervention and the comparison group.} A (desirable) result that indicates FbF beneficiaries experiencing a 10\% lower food expenditure share than the comparison group, on average, will not be meaningful if this difference is “consumed” by a sampling error margin of 15\%.
Because an appropriate sampling strategy is so decisive, it is important to ensure that the FbF team has adequate capacity available to do the sampling. The sampling frame can be prepared with in-house capacity based on existing guidance (see toolbox), or a statistician/demographer is brought on board under contract or through partners to help prepare a sampling approach. Based on the typical FbF intervention sizes and in line with WFP’s guidance for two-stage cluster sampling, it can be expected that the sample size will be between 300 and 600 per group, i.e. a total of 600 to 1,200 interviews will need to be conducted. These figures are for general orientation only and must be calculated for the respective intervention and context.

The research design outline in Annex 6 includes basic sketches of a sampling approach.

3. **Tailor data collection tools to actions, results and context**

The questionnaire design follows the intervention’s ToC and the definition of indicators in the logframe and the M&E plan. The choice and sequencing of questions should also be guided by the assumed pathway of change which the survey results can help to confirm or disprove. Consider two examples:

- **Cash distribution:** Assumed pathway of change (ToC): FbF intervention distributes cash to beneficiaries. → Beneficiaries are able to buy nutritious food. → Beneficiaries will be able to eat more and consistently nutritious food for as long as the money lasts. Monitoring information should already be available to indicate when beneficiaries received the money. The survey can include questions to assess how beneficiaries spent the money (whether primarily on food or other expenses), for how long it lasted, what their current food security status is and whether they relied on adverse coping strategies, and how the latter two findings compare to similarly vulnerable and affected households who did not receive FbF cash assistance.

- **Seed and fertilizer distribution:** Beneficiaries have seeds and fertilizer available. → They will be able to plant at the right time and apply appropriate amounts of fertilizer to ensure fast maturing crops. → Beneficiaries will experience a better harvest than comparison households (a distribution of supplementary animal feed would retrace similar steps but with the result of having healthier animals or less animal mortality at a certain point in time). The survey will include questions on whether and when beneficiaries made use of the FbF supplies, whether the crops matured as planned or any challenges were encountered, and will compare planting and harvesting outcomes between beneficiaries and comparison households.

The draft questionnaire should be field tested, as is standard practice, to ensure that all questions are clear, concepts are universally understood, and response options anticipate the majority of given answers to the extent possible.

**It is advisable to start programming the questionnaire into MoDa or any other electronic data collection platform well in advance of the field data collection.** This will allow the team to make full use of the data validation features of such platforms, test the tool and be sure to have completed the technical setup without rushing, which can lead to errors that are difficult to fix once data collection has begun.
4. Collect data

As the sampling strategy and data collection tools have been developed in previous steps, the primary data collection becomes a significant logistical task that involves:

- Training enumerators
- Planning field work logistics
- Quality assurance of data collection

**Advance planning is essential to have sufficient capacity for data collection available at the appropriate time.** Data is commonly collected by any one or a combination of WFP, partner and government staff who all need to be trained on the questionnaires and data collection protocols.

In case data collection is externalized, partnerships with academic institutions are a promising avenue and can be set up to provide assistance with the sampling strategy; hiring, training and coordinating enumerators for field work; and doing data analysis. Framework partnership contracts can be established during the design phase of an FbF programme and include an activation clause: the main set of tasks of the partnership are only activated when the FbF system is triggered.

5. Analyse quantitative data

At the heart of the quasi-experimental assessment design is the comparison of outcomes between FbF beneficiaries and a comparable group of non-beneficiaries. As indicated under step 2, simple descriptive statistics and frequency counts will be insufficient as they do not take into account the sampling error. Instead, outcome indicators must be tested for statistically significant differences within and between the groups, or their absence confirmed as a sign of potential ineffectiveness of the intervention.

The research design outline in Annex 6 includes a basic example of how a **data analysis plan** can be presented.

The results of the analysis should be reported in whichever format is most suitable to the operational context of the CO. For example, an outcome monitoring report, including charts and data tables, can be produced to provide a detailed account of the analytical results, while shorter or visual summaries may be more appropriate for external audiences (see below).

WFP corporate indicators should be reported through the appropriate channels (COMET).

**Statistical data analysis using a quasi-experimental approach is a technical task with specific capacity requirements.** Likewise, the analysis of qualitative data from focus group discussions (FGD) and key informant interview (KII) – if it is included in the data collection (see C.1 above and step 6 below) – demands a methodological approach and rigour. It is recommended to take stock of the existing in-house capacity – regarding
technical expertise of staff and the availability of suitable software packages – and consider bringing on board additional expertise when required. The most commonly sought profiles are statisticians, demographers or qualitative research specialists.

**Toolbox**
- Research design and analysis plan outline (example in Annex 6)

6. **Conduct Focus Group Discussions to contextualize survey findings**
Outcome monitoring results can bring up surprising or puzzling findings. Even if this is not the case, in-depth qualitative data can help FbF practitioners to **gain a deeper understanding of the disaster experience, needs and perspectives of the affected population**, their coping strategies and why they acted in a certain way.

FGDs can be conducted with a **sub-sample of AA beneficiaries and the comparison population**. The topics for discussion should be informed by the outcome monitoring findings, where issues remain unclear or there is potential for the AA SOP to be improved. The number of FGDs to be undertaken depends on the time, resources and interest of the FbF programme, as well as the scale of the intervention. Typically, the FGDs cover the different geographic areas reached by the AA and different population groups and demographics, if applicable. More detailed suggestions on FGD group composition and size are included in Annex 5.

**Toolbox**
- Focus Group Discussion Guide (example in Annex 5)

**D. Learning**

The primary objective of this document is to support FbF teams in generating data-driven insights about whether and how their interventions make a difference to vulnerable people affected by drought. The conclusions should allow WFP FbF teams to design more effective AA, and enable drought-affected people to cope better with extreme weather events in the future.

1. **Review and interpret data and draw conclusions about the FbF programme**
   Once the process and outcome survey data are analysed and the results are written up, it is important to ensure that this valuable information is used.

   An **After Action Review (AAR)** can be a suitable exercise to reflect on results, guided by the typical AAR questions: (i) What was expected to happen? (ii) What actually occurred? (iii) What went well and why? (iv) What can be improved and how?

   It is recommended to plan for a strategic moment of reflection that allows the FbF team and its partners to engage with and interrogate the findings, and to draw conclusions about how the FbF programme can be strengthened. This can be done as a stand-alone meeting or built into a longer (2-3 days) lessons learned workshop about the FbF activation.

---

26 SPSS and Stata are commonly available, commercial software solutions and can be used for the types of statistical test required for this analysis. R is a free, open-source alternative with equally powerful statistical analysis and visualization functions. Software packages to assist with coding and analysing qualitative data can be found online, some of them for free.
2. **Prepare, share and discuss findings with key audiences, including affected people**

WFP’s [Strategy for Accountability to Affected Populations](#) (AAP) commits the organization to three key activities that are meant to operationalize accountability: information provision, consultation, and complaints and feedback mechanisms (CFM).

It is good practice to design M&E processes not as extractive information gathering exercises but as endeavours of shared learning.

In addition to technical reports and presentations, FbF programmes should **share M&E findings back to the drought-affected populations**. Insights about which adaptation, livelihood or coping strategies have proven to be more successful during the drought conditions can help vulnerable people prepare better and recover faster from the extreme weather event.

The format in which findings are shared should be tailored to the community audience, for example, by oral presentation in group meetings, visual representations of the results, and participatory processes for discussing and reflecting on the findings.
Contribute your tools and insights

Readers are encouraged to share their adapted research designs, questionnaires or analytical results with the PRO-C team. Materials can be added to the growing online repository of tools and benefit FbF practitioners in other countries.
Minimum set of indicators to be included in the logframe

Since every country context and SOP is different, this guidance does not prescribe a common set of indicators that must be monitored for every FbF intervention. It is recommended that standard CRF indicators are included wherever possible (esp. on food security, see ‘ultimate outcomes’ in logframe).

The following indicators are strongly suggested to be monitored, depending on the anticipatory actions and results to be achieved (CRF reference numbers in [square brackets]):

Always monitor:

- Number of people covered and assisted through Forecast-based Anticipatory Actions against climate shocks [G.9]
- Consumption-based Coping Strategy Index (rCSI) [1.1.2/ 3.1.6/ 4.1.2]
- Livelihood Coping Strategy Index (LCS) – stress/crisis/emergency [1.1.2/ 3.1.6/ 4.1.2]

Outcomes, if intended results affect food security:

- Food Consumption Score (FCS) - proportion acceptable/borderline/poor [CRF ref. 1.1.1/ 3.1.5/ 4.1.1]
- Food Expenditure Share - proportion spending >= 65% of monthly budget on food [1.1.3/ 3.1.7/ 4.1.3]

Outcomes, if intended results include asset creation:

- Proportion of the population (%) in targeted communities reporting benefits from an enhanced livelihood asset base [1.1.4 / 3.1.8 / 4.1.4]

If AA includes (a) access to climate/weather information, (b) use of climate resilient livelihoods practices, or (c) climate resilient assets protecting the community against climate related shocks:

- Number of people provided with direct access to information on climate and weather risks [G.8]
- Number of people benefiting from assets and climate adaptation practices facilitated by WFP’s Risk Management activities [G.10]
- Proportion of targeted communities where there is evidence of improved capacity to manage climatic shocks and risks [O. 4.1.6]

Outputs, by type of AA:

- Transfers, general:
  - Number of women, men, boys and girls receiving food/cash-based transfers/commodity vouchers/capacity strengthening transfers [A.1]
  - Number of women, men, boys and girls *with disabilities* receiving food/cash-based transfers/commodity vouchers/capacity strengthening transfers [A.9]

- Food assistance:
  - Quantity of food provided [A.2]

- Non-food items:
  - Quantity of non-food items distributed [A.5]

- Cash transfer:
  - Total amount of cash transferred to targeted beneficiaries [A.3]
FbF M&E Guide

- Total value of vouchers (expressed in food & non-food items/cash) redeemed by targeted beneficiaries [A.4]

- **Asset creation:**
  - Number of assets built, restored or maintained by targeted households and communities, by type and unit of measure [D.1]
Annex 1: Logical framework for a drought FbF intervention (example)

This logical framework is based on the ToC shown in Figure 4a: *Simplified, integrated theory of change of WFP FbF drought projects (see Annex 1 for corresponding logframe with CRF references, including assumptions)* and serves as an example of how indicators, target values, means of verification and assumptions can be established. The indicators and targets in this example are defined so they apply *in the event of a trigger*, when anticipatory actions (AA) have been implemented.

**CROSS-CUTTING CRF INDICATORS – see drought example above**

**Annex 2: M&E plan for a drought FbF intervention (example)**
The M&E plan follows the logframe example (Annex 1). Data collection means and responsibilities should be adapted to the implementation context of the respective intervention. It is very important to note that the timing of when indicator data is to be collected (‘frequency & schedule’ column) depends on the specific anticipatory actions, their timing and the assumptions about when their impacts will have fully materialized.

**CROSS-CUTTING CRF INDICATORS**

**Protection**
- Proportion of assisted people informed about the programme
  - Measure the amount of people that is informed about what WFP has committed to deliver to them and in which ways
  - Survey & Programme records
  - After every AA activation
  - Lead responsible for surveying & WFP programme staff / implementing partner

**Accountability to Affected Populations**
- Proportion of targeted people receiving assistance without safety challenges
  - “Safety challenges” refer to any act of violence, injury, coercion, abuse or intimidation or deliberate deprivation by any actor which undermines a person’s safety.
  - Survey
  - After every AA activation
  - Lead responsible for surveying
- Proportion of targeted people who report that WFP programmes are dignified
  - “Dignity” is intended as self-determination, respect for aspirations and wishes, self-worth. Protection challenges affecting dignity include disempowerment, humiliation and disrespect.
- Proportion of targeted people having unhindered access to WFP programmes
  - “Access” refers to people’s access to WFP programmes and assistance. This includes access to where WFP is implementing an activity as well as the areas beneficiaries have to travel to and from to access these sites.

**Linkages to financial resources and insurance services facilitated**
- Number of people benefiting from assets and climate adaptation practices facilitated by WFP’s Risk Management activities [G.10]
  - Counts the number of people benefiting of trainings on climate adaptation management practices and assets
  - Programme records
  - Immediately after training
  - Training implementer & WFP programme staff / implementing partner

Annex 4: Timing of data collection decision matrix

This matrix is designed as a decision aid to record assumptions, the rationale and conclusions about the best time to implement AA and collect results data. It can be filled in as a desk-based exercise, or to facilitate a discussion among the FbF team, or in consultation with drought-affected community members.

How to fill the columns:

A. **Action description**: The anticipatory action to be implemented when the FbF system is triggered, and the duration of how long it will take until the action is fully implemented (i.e. all targeted beneficiaries reached). If it is a recurrent action, note down the frequency and periodicity of implementation.

B. **When, in relation to seasonal calendar**: The time when the action should be implemented in the seasonal calendar to have the greatest likelihood of yielding the maximum benefit for beneficiaries, for example, “at the beginning of the raining season”, or “as late as possible in the growing season”. In case the seasonal timing is not relevant, please also provide a short description of the rationale, for example, “not relevant because food distribution will have maximum positive impact whenever there is a severe nutrition crisis”.

C. **When, in relation to agricultural activity**: The time when the action should be implemented in the agricultural calendar to have the greatest likelihood of yielding the maximum benefit for beneficiaries, for example, “as early as possible in the planting season”, or “immediately before the harvest starts”. Also note rationale if not relevant.

D. **When, in relation to anticipated disaster impacts (drought, flood, cyclone)**: The timing of action implementation in relation to socio-economic or agricultural conditions that are relevant for the decision to act, for example, “as soon as water reservoir levels drop below 15%”, or “as soon as Integrated Phase Classification (IPC) phase 4 (emergency) is reached indicating large food consumption gaps”.

E. **What is the expected result / benefit** of the action for beneficiaries, for example, for a seed distribution “fast-maturing seeds allow harvest within 2 months of planting and yield on average 3 months' worth of food supply”, or for a cash-based transfer “beneficiaries can afford buying sufficient food for the household lasting 2 months”.

F. **When, “first signs”** of the result(s) are observable, for example, for a seed distribution “within 2 weeks of the start of the harvest season, approx. 8 weeks after planting”, or for a cash-based transfer “within two weeks of the distribution, when households will definitely have made the first purchases”.

G. **When, “fully materialized”** results are expected to be observable or can be recalled by the beneficiaries without a long period of time having passed in the meantime, for example, for a seed distribution “at the end of the harvest season, on average 12 to 16 weeks after planting”, or for a cash-based transfer “8-12 weeks after the distribution when beneficiaries can be expected to have spent the majority of the cash and food security results should be observable or recallable”.

H. **Method of data collection**, for example, a “face-to-face survey of beneficiaries and a comparison group across 4 districts”, or “phone survey of beneficiaries and a roster of pre-identified comparison households”.

I. **When, earliest and latest**: Columns I and J (earliest and latest time of data collection) should be primarily decided based on column G (results fully materialized). However, it is important to consider that a protracted drought situation may continue for longer than the AA assistance was designed to “withstand”. Therefore, results can be expected to “disappear” after a period of time if the extreme conditions and vulnerabilities persist. To measure
immediate effects, the ideal window of opportunity for results data collection is *as soon as* results can be expected to have fully materialized and within 4-8 weeks. The more time passes between intervention/benefit accrual and survey, the greater the recall bias will be (people are likely to forget or misremember). To measure medium-term effects, including whether benefits “lasted” or when they “ran out”, repeat surveys can be undertaken, for example, in an interval of 3-6 months.

J. **When, latest**: See column I.

Annex 5: Focus Group Discussion (FGD) guide (example)

Objective:

Once outcome monitoring data have been analyzed, the purpose of the follow-up FGDs is to contextualize the quantitative survey findings to understand why respondents answered in a certain way. For example, the outcome data might show that cash transfer beneficiaries spent most of their money on something that the FbF intervention did not foresee. Understanding why this was the case can help the FbF programme adjust its targeting or the selection of anticipatory actions, if it turns out that cash is not the most efficient means to address the need of the beneficiaries.

Please note: Instructions for FGD preparation (including on group composition) and “useful tips for the FGD facilitator” have been included below the FGD script.

**FOCUS GROUP SCRIPT**

*(Welcome)*

The moderators introduce themselves to the participants.

- Name
- Background

*(Purpose)*

We are speaking with you today to learn about your experiences during the recent [drought/flood/cyclone]. This will help us and others to be better prepared to provide assistance in the future.

Your answers will not impact whether or not your community receives WFP assistance in the future, so it is important to be honest with us and tell us how you really feel and what is most important to you.

Our discussion today will last about 60 to 90 minutes (one-and-a-half hours).

*(Ground rules)*

Our role will be to ask a number of questions and listen to your answers.

We would like you to do the talking. We would like everyone to participate and will make sure everyone has time to speak. We may call on you if we haven’t heard from you in a while.

There are no right or wrong answers. Every person’s experiences and opinions are important. Please speak up whether you agree or disagree. Some people might not think the same things as you do, and that is OK. We would like to hear a wide range of experiences. We hope that all of you will share their views and tell us what you think.

If you have any questions while we are talking, please let us know.

*(Voluntary)*
FbF M&E Guide

It is important that you know you do not have to talk with us today. It is okay to choose not to talk with us. If you choose to talk with us today, you can decide not to answer every question. Also, you can stop talking when you want to.

(Confidentiality)

We will not share your specific answers with anybody. It is important that you do the same thing. It is important that you do not share anything that is said by anyone in this group with anybody outside of the group.

We will share the information in a way that does not let people know who came to this group today, or who said what. Your name will not be on any reports or presentations that we will produce.

(Audio recording etiquette)

You may see us writing things down; this is so we don’t forget anything we talked about. We are also audio recording our talk today so that we will be able to remember exactly what you tell us. In order for the audio recording to work well, only one person can talk at a time so that we can hear everything that everyone says.

Does anyone have any questions about what I just talked about? Let’s begin…

FOCUS GROUP DISCUSSION PROTOCOL

Example for AA cash beneficiaries

Discussion start time: __________________

IMPORTANT:
WHEN ASKING A QUESTION, DO NOT READ OUT PROBES IN [SQUARE BRACKETS] IN THE BEGINNING; THESE ARE PROMPTS TO BE USED IN CASE PARTICIPANTS DO NOT MENTION THESE ISSUES DURING THE DISCUSSION.

[Icebreaker question (5-10 minutes):]

1. To begin, I would like to go around and have everyone share briefly what was the first thought that crossed your mind as you woke up this morning?
   
   ● [Ask a volunteer to start, then go around the group and make sure everyone speaks.]
   ● [Keep answers brief.]

[Core questions (50-70 minutes):]

2. Tell us about the recent [drought/flood/cyclone].
   
   ● What happened?
   
   ● Was there anything different in how you experienced the most recent [drought/flood/cyclone] event compared to previous [drought/flood/cyclone]? Was it more or less severe?

   [Probe - in case participants do not bring this up during the discussion:]
   
   a) [If participants mention more or less severe, let them qualify these statements HOW / WHY they say it was more or less severe.]
   
   b) [Probe for differences in timing, severity, scale]

3. Before the recent [drought/flood/cyclone] happened, did you learn in advance that this time the [drought/flood/cyclone] would happen, and whether it would be more severe than usual? How?

   [Probe - in case participants do not bring this up during the discussion:]
   
   a) [Probe whether an early warning was received?] 
   
   b) [When was information / warning received?]
   
   c) [Were people warned earlier / later than usual? Did this make a difference?]
   
   d) [How was weather or warning information obtained? Through which channels? From whom?]
4. Did you take any actions to prepare and protect yourself, your homes, your livestock or your farms against the impact of the [drought/flood/cyclone]
   - before it happened? What did you do?
   - during the time when the [drought/flood/cyclone] had already started happening?

   [Probe - and note whether actions were taken BEFORE or DURING the [drought/flood/cyclone]:]
   a) [Did people sell valuable assets to get cash? What did they sell, and for what purpose?]
   b) [Did people borrow money from someone / take out loans? For what purpose?]
   c) [Did people evacuate?]
   d) - [Where did they evacuate to?]
   e) - [When did they evacuate?]
   f) - [Any challenges when evacuating?]

5. Which [drought/flood/cyclone] impacts are worrying you most?

   [Probe - in case participants do not bring this up during the discussion:]
   a) [Damage to housing / physical infrastructure?]
   b) [Loss of livestock?]
   c) [Health of self or family members?]
   d) [Inability to work / loss of income? For how long?]
   e) [Need to borrow money / accrue debt?]

   [The following section probes about surprising or puzzling findings from the outcome monitoring survey (insert as necessary):]

6. Some of you may have recently participated in a survey whereby someone came to your house or called you on the phone to ask you about your recent [drought/flood/cyclone] experience. We learned that many of you spent most of their cash assistance on [__________]. Can you tell us why this is the case? Has anyone spent it on something else?

7. [Insert additional questions about puzzling findings]

   [The last question is about the preferred type of assistance which is perceived to be most useful to help avoid/mitigate negative [drought/flood/cyclone] impacts.]

8. If such severe [drought/flood/cyclone] were to happen again in the future, what type of assistance would be most helpful to you to be prepared?

   [Probe - in case participants do not bring this up during the discussion:]
   a) [Early warning?]
   b) [Cash assistance?]
   c) [Distribution of goods / assets?]
   d) [Evacuation assistance?]
   e) [Anything else?]

   [Closing question (5-10 minutes):]
9. Is there anything else you would like to share with us regarding your experiences with the recent flooding?

(Closing)

Thank you for sharing your experiences and opinions with us. You have been very helpful and we appreciate you taking the time to speak with us.

Discussion end time: ___________

Total duration: _______ minutes

[Immediately after all participants leave, the moderators debrief while the audio recorder is still running and label all recordings and notes with the date, time (if more than one group per day), and name of the group.]

FGD PREPARATION

Resources needed:
- 2 moderators (1 facilitator, 1 note-taker)
- Audio recorder (tape or digital; can be a smartphone)
- Notepads, pens for note-taker

Moderators:
The ideal focus group facilitator has the following traits:
- Can listen attentively with sensitivity and empathy
- Is able to listen and think at the same time
- Believes that all group participants have something to offer no matter what their education, experience, or background
- Has adequate knowledge of the topic
- Can keep personal views and ego out of the facilitation
- Is someone the group can relate to but also give authority to
- Can appropriately manage challenging group dynamics

The note-taker must be able to do the following:
- Set up a tape recorder and check that it is recording well
- Run a tape recorder during the session
- Take notes; this is very important in case the recorder fails or the tape is inaudible (which is often the case because some participants speak very quietly)
- Note/record body language or other subtle but relevant clues
- Allow the facilitator to focus on moderating the group and do all the talking during the discussion

Participants:
In each community (FbF intervention and comparison), 2 FGDs should be organized:
- 1 FGD with men (6-10 participants)
- 1 FGD with women (6-10 participants)
A discussion group should **not exceed** the maximum of 10 participants. **Bystanders should not be present**, meaning the group should have a quiet space to discuss undisturbed among themselves.

**Group composition:**
FGD participants should be **selected by the moderators, in consultation with** the appropriate community leaders. Selection of participants should **not** only rely on willing community members volunteering to participate as this may lead us to miss the voices of the most vulnerable / less vocal community members.

**Priority groups** to be included in FGDs: FbF cash recipients (in FbF intervention areas); landless; elderly; disabled.

Discussion groups should be demographically **homogenous**: FGD participants usually feel most comfortable sharing their views if they speak among peers. This means a group should not be too diverse regarding the **age range** of participants (avoid putting very young and very old persons together in the same group) and their **vulnerability** (avoid mixing very poor and well-to-do individuals in the same group). To ensure we capture the views of all relevant demographic groups, we need to balance participation across communities: if you have spoken to a group of mostly elderly women in community A, try to speak to a group of mostly younger women in community B.

**USEFUL TIPS FOR THE FGD FACILITATOR**

**Keep time:** The focus group moderator has a responsibility to adequately cover all prepared questions within the time allotted.

**Probe for more:** The facilitator also has a responsibility to get all participants to talk and fully explain their answers. Some helpful probes include:

- “Can you talk about this a little more?”
- “Please help me understand what you mean.”
- “Can you give an example?”

**Summarize:** It is good moderator practice to paraphrase and summarize (repeat in your own words) long, complex or ambiguous comments. It demonstrates active listening and clarifies the comment for everyone in the group.

**Remain neutral:** Because the moderator holds a position of authority and perceived influence, s/he must remain neutral, refraining from nodding/raising eyebrows, agreeing/disagreeing, or praising/denigrating any comment made.

**Actively moderate:** A moderator must tactfully deal with challenging participants. Here are some appropriate strategies:

- **Self-appointed experts:** “Thank you. What do other people think?”
- **The dominator:** “Let’s have some other comments.”
- **The rambler (doesn’t stop talking):** Stop eye contact; look at your watch; jump in when they inhale.
- **The shy participant:** Make eye contact; call on them; smile at them.
- **The participant who talks very quietly:** Ask them to repeat their response more loudly.
More useful guidance can be found here: Mack et al. (2005), *Qualitative research methods: A data collector's field guide*. Module 4 (p.51-82) covers Focus Groups in detail.
Annex 6: Research design and analysis plan outline (example)

Assessing household-level effects of forecast-based assistance to vulnerable households in anticipation of <drought/flood/cyclone> in <name of country/region>

1. Background
[Describe the FbF programme context in your country, the trigger methodology and the actions to be implemented when the SOPs are triggered.]

2. Purpose
[Describe the objective of the research, for example:]
The objective of this assessment is to understand the extent to which forecast-based cash assistance in anticipation of <drought/flood/cyclone> in <name of country> is effective in improving the food security and avoidance of negative (food-based) coping strategies among beneficiary households.

3. Research question(s) / hypotheses to be tested
[Formulate clear research questions to be answered by the assessment, or hypotheses to be tested, for example:]
This study will investigate the following hypotheses about the effectiveness of AA:

- H₁: FbF beneficiary households experience significantly higher food security, as measured through the FCS, after the <drought/flood/cyclone> compared to equally disaster-affected and vulnerable households without FbF assistance (comparison group).
- H₂: A significantly lower proportion of FbF beneficiaries uses food-based coping strategies, as measured through the rCSI, compared to non-FbF-assisted households.
- H₃: FbF beneficiaries whose main livelihood is based on livestock experience significantly lower animal mortality rates compared to the comparison group without FbF assistance.
- H₀: There is no discernible difference in the outcomes of FbF beneficiaries and non-beneficiaries (null hypothesis).

4. Study design
[Describe the design of the study, whether quantitative, qualitative or mixed, and how the hypotheses will be tested/assessed, for example:]
This assessment uses a quasi-experimental study approach, comparing FbF beneficiaries with a comparison group of equally vulnerable and <drought/flood/cyclone> affected households in the same geographic area. ...

[Note that different study design may be feasible, depending on several factors, including whether baseline data collection is possible (allowing for a DiD approach); whether randomization of the assignment of communities or households to the FbF intervention is possible (a precondition to conduct an RCT); the available budget and logistical resources which will influence the viable sample size; among others. Common to all study designs will be attempts to control for bias in the data. For example, Propensity Score Matching (PSM) and Regression Discontinuity Design (RDD) are two common approaches used with quasi-experimental designs to control for selection bias. Each bias correction and matching method has different strengths and weaknesses; discussing the trade-offs would go beyond the scope of this example. Recommended reading: White, H. (2013), An introduction to the use of randomised control trials to evaluate development interventions]
5. Study population and sampling

[Describe the population of interest and involved in the study. See also the WFP Sampling Quick Guide. This will typically include a detailed description of the targeting criteria which can be taken from the SOPs, for example:]

The study will compare FbF beneficiaries (the intervention group) with a comparison group of non-beneficiaries. Both groups will consist of highly vulnerable smallholder farmers in <district A>, <district B> and <district C>. It is envisaged that the FbF intervention will be implemented in the 100 most vulnerable communities across the 3 most <drought/flood/cyclone>-affected districts, reaching a total of approx. 5,000 households.

Intervention communities are selected based on the following criteria:

- Criteria A: <e.g. livelihood options>
- Criteria B: <e.g. food security scores>
- Criteria C: <e.g. average rainfall over the past 6 months>
- ...

Beneficiaries within the intervention communities are selected into the FbF intervention based on the following eligibility/targeting criteria which are assessed by means of a mini household survey:

- Criteria A: <e.g. asset poverty, assessed through PMT>
- Criteria B: <e.g. high dependency ratio>
- Criteria C: <food insecurity>
- ...

A two-stage cluster sampling approach will be used to select study participants from the FbF intervention group and a comparison group (i.e. two sample populations).

For each group, we estimate a sample size of 450 households to be sufficient to yield results with an error margin of 5% and a confidence level of 95%, balancing the need for a higher sample size due to the greater design effect in two-stage cluster sampling with the shortage of funds for survey data collection (the ideal sample size would be 600 per group, see the WFP Sampling Quick Guide and Raosoft Sample Size Calculator). This means that a total of 900 interviews will have to be conducted.

**Intervention group (FbF beneficiaries):**

- In the first stage of sampling, 30 communities will be randomly selected with probability proportional to size.
- In the second stage of sampling, beneficiary households will be randomly selected from each community to participate in the survey, with the number of households per community proportional to size.

**Comparison group (without FbF assistance, and/or benefitting from conventional humanitarian response):**

- Since the FbF intervention is implemented in the 100 most vulnerable communities across the 3 districts, two strategies are available to select comparison communities:
  - (a) Draw up a list of the 100 next most vulnerable communities in the same 3 districts (which will be slightly less vulnerable than the intervention communities).

---

---

27
(b) Draw up a list of 100 equally vulnerable communities from neighbouring districts that fulfil the following criteria: (i) the FbF intervention is not implemented there, nor any other intervention that is not also implemented in the intervention communities; (ii) communities are equally <drought/flood/cyclone> affected; (iii) the community population shares the same socio-economic vulnerabilities as the intervention group.

- We opt for option (a) since the vast majority of communities in the 3 intervention districts are extremely vulnerable and differences between communities are very small. Moreover, there is practically no risk of 'sample contamination' as the cash transfer amount is not large enough to be likely to influence market prices in the area, and benefits are not expected to leak to non-beneficiary households.
- The first stage of sampling involves drawing a random sample of 30 of the 100 next-most-vulnerable communities in the 3 FbF districts.
- In the second stage of sampling, a household listing using the FbF eligibility criteria will be carried out in each of the 30 selected comparison community. From the list of eligible households, a random sample of survey participants is drawn with their number proportional to size.

6. Data collection methods and instruments

[Describe which data collection methods and instruments will be used in the assessment, for example:]

a) Household survey (quantitative): A household survey will be conducted among beneficiary and comparison households included in the sample (see above). The survey will ensure that 50% women and 50% men will be interviewed. The household questionnaire is attached in <Annex X>.

b) Focus group discussions (qualitative): From each group (intervention and comparison), 10 communities will be randomly selected. Two focus group discussions (FGD) will be organized in each community, one with women and one with men. The FGD discussion guide is attached in <Annex 5>. The primary purpose of the FGD is to contextualize the quantitative information and yield rich qualitative insights not obtainable otherwise, including answers to some of the emergent 'why' questions.

c) Key informant interviews (KII): In the 10 communities (each) in which FGDs are conducted, two KIIs will be conducted. One KII will interview the local agricultural extension worker about <drought/flood/cyclone> conditions and agricultural activity, the second KII will be held with a member of the local water management committee. The KII semi-structured questionnaires are included in <Annex Z>.

7. Data analysis methods

[Describe which data analysis methods will be used and the main variables of interest, for example:]

a) Household survey (quantitative): Statistical analyses will be performed on the quantitative dataset including
- Exploratory data analysis and data cleaning
- Descriptive statistics and sample means analysis of the main socio-economic predictor variables to assess the comparability of the two groups (intervention and comparison)
- Statistical balancing of sample imbalances between the two or more groups, for example, through Propensity Score Matching (PSM), or use of bias-corrected matching estimators using nearest-neighbour matching (to mention some among other possible options to control for bias in the data; the choice also depends on the structure of the data and the experience of the analyst)
- Hypothesis (see above) testing by assessing outcome variables for statistically significant differences between the treatment and comparison groups
b) **Focus group discussions (qualitative):** FGDs will be transcribed verbatim and coded for patterns using standard qualitative software analysis tools (such as QDA Miner or Dedoose).

c) **Key informant interviews (KII):** KIIs will be transcribed verbatim and equally coded for patterns. An inductive approach will be taken to identify information relevant to the interpretation of survey or FGD findings and to assist in tracing causal attribution of results to the FbF intervention (or not).

8. **Quality assurance mechanisms**

Quality assurance mechanisms are particularly relevant for survey enumerator training, field data collection and analysis. It is also critical to ensure professional facilitation of FGDs and KIIs to avoid leading questions, bias due to power dynamics, etc., for example:

a) **Household survey (quantitative):** It is envisaged that a team of 10 enumerators and 3 field supervisors will be needed for data collection. 15 enumerators will be trained and assessed during the 2-day training. Only the 10 most suitable enumerators will be deployed for data collection, with the 5 less suitable remaining as backup options.

   Interviews will be facilitated and data entered via the MoDa mobile data collection platform, enabling supervisors and the M&E focal point in the CO to have a live overview of the income data.
   Data submissions will be spot-checked daily to ensure quality and consistency.

b) **Focus group discussions (qualitative):** FGD facilitators will have to have undergone facilitation training and be experienced in leading inclusive group discussions that allow all participants to have their voice heard.

c) **Key informant interviews (KII):** Interviewers will have to have undergone interview training and be experienced qualitative researchers to be able to prompt when appropriate, give room for elaboration when needed, and avoid asking leading questions.

9. **Ethical considerations**

Population-based surveys or any form of data collection involving people may require ethical clearance, depending on local protocol. When collaborating with implementing partners or universities, it is recommended to ensure they subscribe to and follow all ethical research standards. Universities often have Ethics Review Boards (ERB) and it is recommended to subject the research design and tools to ERB review, for example:

The assessment follows WFP’s code of conduct and the UNEG Ethical Guidelines. Moreover, informed consent and ‘do-no-harm’ principles form the basis of this assessment.

10. **Resources required**

It is suggested to estimate and set aside a realistic budget amount for the impact assessment, based on previous experiences with the cost of surveys and qualitative research in the local context. Costs vary considerably by country; also include non-financial resources that may be contributed in-kind by WFP or partners, for example:

- **Total impact assessment budget:** <enter amount in USD or local currency> (see <Annex X> for detailed budget)
- **Non-financial resources:**
  - 13 tablets for mobile data collection using MoDa (10 enumerators + 3 field supervisors): will be borrowed from the National Statistics Office free of cost
  - The WFP CO will provide 3 vehicles including drivers and fuel costs (not included in above budget) to facilitate data collection field work

11. **Target audience, presentation of findings**

Describe who will be the primary users of the study findings, which will inform the preparation and presentation of results; clarify expectations whether a detailed written report is required or essential.
statistical and qualitative result information will be sufficient and can be provided in tables and charts only; for example:

- **WFP FbF programme team**, to learn about the effectiveness of AA and to improve the SOPs. Format for presentation of findings: document containing all key statistical tables and charts, which a few sentences summarizing the key take-aways for each visual.
- **External partners**, to learn about the FbF intervention and its effects. Format: a slide deck (PowerPoint) of mainly charts with one-line summaries of key take-aways.
- **Study participants (treatment and comparison group)**, to ensure we are accountable to them, share our learnings and provide an opportunity for feedback. Format: a maximum of 10 printed pictorial illustrations of key findings, delivered during 2-hour (approx.) community meetings in a sample of intervention and comparison communities.

12. **Annex (questionnaires, ethical clearance, etc.)**

   [Include questionnaires; FGD and KII interview guides; budgets; inventory lists; and anything else relevant to the assessment.]
Annex 7: Lessons learned session or workshop guidance

Guidance and agenda (example) for an interactive learning exercise

What is the purpose of a lessons learned session/workshop about anticipatory action?
The overall goal of this learning exercise is to contribute to the understanding of the FbF team and its partners about the performance of their anticipatory actions and associated processes, and to help promote learning and accountability.

Following the implementation FbF anticipatory actions, and ideally the analysis of outcome survey/impact assessment data, the exercise typically takes a 1-3 day workshop format and brings together all key staff and stakeholders involved in financing and implementing the anticipatory actions in anticipation of drought/flood/cyclone.

More specifically, the learning exercise can:
- Provide space for implementers and partners to engage with, interrogate and interpret the M&E findings, drawing data-driven conclusions about what the anticipatory actions achieved and where they fell short of expectations;
- Share experiences and perspectives about what went well and where there is room for improvement;
- Identify recommendations to the FbF team (management, staff and partners) for improving the SOPs and/or other anticipatory action-related plans and decisions.

Overall questions for reflection that frame the exercise:
During the learning exercise, the following questions can help you to reflect on the performance of the SOPs and draw lessons learned:
- What do the data and the qualitative beneficiary feedback tell us about the effectiveness of the anticipatory actions? Have they achieved their goals?
- What worked well in our actions, and why?
- What did not work well, and why?
- What should we replicate and scale up, and what do we need to do differently in such situations?

Thematic areas for learning:
Every SOP activation will be different, depending on the hazard and geographic context. Therefore, the learning exercise should focus on areas of learning that are most relevant for the local context. Areas to consider are:

a. The different components of an SOP activation:
   - SOPs development, including trigger definition / analysis and use of forecast information (planning)
   - Anticipatory action selection and implementation (activities)
   - Effects of the anticipatory actions on the target population (outcomes / results)

b. The operational dimensions of the activation:
   - Logistics planning, preparedness and implementation
   - Financial management
   - HR, staff and implementation team / volunteers
   - Data collection, monitoring, information management
   - Assessment, analysis & decision making
   - Safety and security

---

28 Adapted from Red Cross Red Crescent Climate Centre (2019), FbF M&E Guide: Lessons learned from activation.
Who should be involved?
It is important to involve all key individuals who can meaningfully contribute to learning about the recent SOP activation. Typically, this includes:

- WFP FbF team and management;
- SOP implementing partners (with experience from field-level actions, not only office staff/management);
- Forecast providers (e.g. meteorological agency representatives);
- Government disaster preparedness/response agencies or other partners involved in the SOP process;
- Other humanitarian agencies with similar interventions;
- Representatives from the financing organization, as applicable.
- Representatives of drought-affected/beneficiary populations.

Which preparations are needed?
It is recommended to compile all the available data about the recent activation, including but not limited to:

- Forecast information & weather data based on which the SOPs were triggered, and data on the extreme event (e.g. wind speeds; water levels; rainfall intensity; etc.);
- SOP implementation monitoring data;
- Outcome survey data;
- Secondary data sources about impacts of the weather event (e.g. crop losses; water availability; rainfall conditions, etc.).

Which other resources are available?
It is recommended to structure the content and process of the exercise according to the local learning priorities. The internet is full of helpful resources on learning workshops and after-action reviews, including for the international development and humanitarian fields. One recommended resource is ODI’s Tools for Knowledge and Learning: A Guide for Development and Humanitarian Organisations.

Agenda (example)

Note on group work: Whenever “group work” is suggested, a large participant group should be organized into group tables or similar. If only a small number of people participate in the workshop, then the exercises may be done in plenary.

<table>
<thead>
<tr>
<th>Day 1</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Introduction</strong></td>
</tr>
</tbody>
</table>
| *Purpose:* Participants get to know each other and the objectives for the workshop | *Warm up get-to-know-each-other exercise*  
  - Introduction of workshop flow and methodology  
  - Group exercise: Introduction of participants & expectations (1 desired take away per person on a piece of paper, then table groups discuss these among themselves)  
  - Facilitator collects expectations (on paper) and organizes them on the wall for later sharing (if the group is small, this can be done immediately in plenary) |
### Session 1
**Timeline exercise**

**Purpose:** Create a common understanding of “what happened and when”; can be done from scratch or with a core timeline prepared
- Suggestion: begin with a short presentation on “what happened” to summarize the main facts (key disaster events, number of people affected, where, main impacts)
- Put a series of flipchart papers on the wall and draw a timeline
- Group work: Let participants identify & note key events on cards. One event per card. Three different colors are suggested:
  - Color 1: Natural (weather / disaster-related) events
  - Color 2: External event (e.g. actions taken by people, organizations, etc.)
  - Color 3: Internal event (e.g. SOP decisions, actions, finances, …)
- Reconvene in plenary; a representative from each table places the cards on the timeline, with the help of the facilitator
- Plenary discussion: review timeline, identify enablers / obstacles / critical problems or breaking points

### Session 2
**Reflecting on forecast, trigger and the link to action**

**Purpose:** Understand how good the trigger model and the forecast was, and to what extent the information was analyzed, understood and acted upon.
- Organize the group by area of expertise/task (e.g. forecasters, field implementers, programme managers)
- Let each group reflect on:
  - Did the impact-based forecast reflect actual events on the ground?
  - How timely was the information?
  - How useful was the information?
  - Were there any problems with the forecast / trigger?
  - Do we have new information that can help us refine/improve the trigger
- In plenary, let the groups share their reflections with each other and identify any discrepancies in perceptions → what can we learn from our common understanding and our differences?

### Session 3
**Reviewing the SOP implementation**

**Purpose:** Participants reflect on the implementation of the SOPs and identify what worked well, what did not work so well, and why.
- Questions for reflection (either in groups by question, or in plenary):
  - Were the anticipatory actions clearly defined?
  - Were roles and responsibilities clearly defined? (Suggestion: note down the key roles involved in the SOP implementation and check for each role, e.g.: logistics team, volunteer coordinator, field volunteers, finance, M&E, management)
  - Did everyone do what they were supposed to do, vis-a-vis the plan? (again, go through the roles/functions)
  - To what extent were the anticipatory actions, suitable and appropriate to the disaster situation?
  - What were the main problems? (assess by internal and external causes of the problem)
  - What were the main opportunities that enabled the work (internal/external, lucky coincidence/designed-for)?
### Session 4: Assessing what we know about the effectiveness of actions and impacts

**Purpose:** Assess to what extent the anticipatory actions achieved their objectives, and whether unintended effects were observed

- First, begin with a short presentation on the selection of anticipatory actions and theory of change (what were the actions meant to achieve)
- Second, a short presentation (e.g. by M&E focal point) of the available data on (a) implementation monitoring, (b) beneficiary impacts (survey / secondary data)
- Group work: For each action, reflect on
  - What were the main disaster impacts (in the intervention area)?
  - What effects did the anticipatory actions have, intended or unintended,
    - On physical assets and structures?
    - On the health and well-being of the target population?
    - On the economic activity or status of the population?
    - Any other effects?
    - How do the effects match with what the actions were meant to achieve? Is this over- or under-achievement?
  - Are there any observable differences between people who received anticipatory action assistance and people who didn’t? What can we infer from the differences about the effectiveness of the intervention?
- Plenary reflection on key learnings about effectiveness and impact

### Session 5: Consolidating our learning

**Purpose:** The participants create a synthesis of the main learning points from each session and prioritize areas for improvement

- Group work, e.g. by thematic areas for learning (see first page): Let participants prioritize their most important take-aways from sessions 2, 3 and 4.
  - Identify main problems in each area (internal + external)
  - Identify main opportunities/enablers in each area (internal + external)
  - Identify linkages between sessions 2, 3, 4, i.e. between forecast/trigger, operations/implementation/management/finance, and monitoring and impact evaluation.
- Let participants summarize their key learnings for each thematic focus area
- For each area, identify the main issues that need improvement/change

### Session 6: Planning to improve - next steps

**Purpose:** For each thematic focus area, participants draw up a concrete action plan for how to implement the necessary changes

- Group work: For each thematic focus area, reflect:
FbF M&E Guide

<table>
<thead>
<tr>
<th>What needs to change?</th>
<th>Who needs to take action to achieve the change?</th>
<th>Who takes the lead / coordinating responsibility?</th>
<th>By when?</th>
<th>What are the resources (people, materials, finances) to make it happen?</th>
</tr>
</thead>
<tbody>

</tr>
</tbody>
</table>

- After the workshop, the organizers synthesize the plans into one consolidated improvement action plan

Wrap-up

Summary of day 2, closing reflections, overall workshop evaluation

Note: The duration of sessions 2 through 5, i.e. the core learning and reflection sessions, can be designed according to your learnings needs. One session could be done in as little as 1.5 hours or half a day each.

Acknowledgements

WFP gratefully acknowledges the funding support received from the Norwegian Ministry of Foreign Affairs (NORAD) and the Danish International Development Agency (DANIDA) for advancing anticipatory humanitarian action for drought in the Africa region and for preparing this monitoring and evaluation guidance document.

This M&E Guide was prepared by Clemens Gros and Dorothy Heinrich under the overall leadership and guidance of Jesse Mason, Paris Kazis and Shirin Merola, Climate and Disaster Risk Reduction Programmes Unit. Special thanks are owed to the FbF programme teams in the WFP Country Offices in Ethiopia, Madagascar, Mozambique, Niger and Zimbabwe who provided their insights and experience which informed the writing of this guide. The authors would also like to thank the WFP colleagues in headquarters for the guidance and support.
